

Recent trends in higher education applications and acceptances

Andrew Abbott*

and

Derek Leslie

ABSTRACT: Using a data set published by the Universities and Colleges Admissions Service (UCAS), patterns of demand and supply for higher education courses from 1996-97 to 1999-00 are analysed. Most universities saw a fall in applications and enrolments following the introduction of tuition fees and maintenance loans, though this effect varies across institutions and regions of the UK. A model of applications and acceptances is developed and tested. Applications are sensitive to each institutions entry standards, reputation and location in the UK. Acceptances depend on teaching funding per head and the number of funded places each institution is given.

Introduction

This paper identifies the recent trends in Higher Education (HE) recruitment, mainly through a data set published by the Universities and Colleges Admissions Service (UCAS). A series of total applications and acceptances from 1996-97 to 1999-00 is constructed for 97 leading UK universities. Patterns of applications and acceptances are compared over time, between institutions and regions of the UK. Although interesting, broad patterns alone cannot explain why some institutions are more popular than others and if students are attracted to particular regions. Because applications and acceptances are part of a larger system, a model of applications and acceptances is developed and estimated. This helps cast light on the impact, if any, of tuition fees, which were introduced in 1998/99.

From the mid 1980s, HE in the UK experienced a rapid expansion. Between 1983-84 and 1993-94, there was a 54% growth, with the majority taking place among full-time undergraduates, which grew by 67% (HEFCE, 2001a) (see figure 1). After this, growth was more modest, with total student numbers increasing by 6% between 1996-97 and 2000-01. The main cause of this expansion was the growth in the number of 18-21 year olds taking university courses. The age participation index rose from 15% in 1983-84 to 30% in 1993-94

(see figure 2). Participation by mature students has also increased. An ambitious target of 50% participation for the 18-30 age group has been set by the government for 2010. However, which qualifications are to be included in the definition of HE (THES, 2001) is still being reviewed. This may make any comparisons with the above trends spurious.

Figures 1 and 2 near here

HEFCE (2001a) suggest a number of reasons for the growth in student numbers. First, the introduction of the General Certificate of Secondary Education (GCSE) in 1988 (normally taken by students at age 16) improved the staying-on rate after compulsory schooling, through an increase in academic attainment at 16 (see also McIntosh, 2001; McVicar and Rice, 2001). Secondly, structural changes in the UK economy, particularly the expansion of the service sector, increased the demand for graduate labour. Managerial class employment has increased while the number of unskilled jobs has fallen. Moreover, some traditional non-graduate jobs have been upgraded to graduate status, since they are now more likely to be filled by degree holders. One reason for the rise in income inequality from the late 1970s onwards has been the rise in the graduate premium over less qualified labour and there is greater awareness that 'graduateness' is a key factor in labour market success (see Blundell *et al.*, 1997). High unemployment in the 80s and early 90s was also an important push factor, especially for ethnic minorities who are strong demanders for HE (see Johnes and Taylor, 1989; Leslie and Drinkwater, 1999; Leslie *et al.* 2002).

Teaching funding is allocated to UK universities according to the number of students each recruits. Recruitment targets have increased since the mid 1980s. For example, the Maximum Aggregate Student Number (MASN)¹ set by the Higher Education Funding Council of

* Andrew Abbott, Department of Economics, the Manchester Metropolitan University, Mabel Tylecote Building, Cavendish Street, Manchester, UK, M15 6BG. Tel: +44(0)161 247 6484; Fax: +44(0)161 247 6302; E-mail: a.abbott@mmu.ac.uk.

¹ The MASN is a cap on the number of full-time undergraduate and teacher training students that each institution can recruit. In late 2001, the government was considering removing this cap, so that institutions would be free to recruit as many students as they wish (The Times, 2001).

England (HEFCE) for all HE Institutions (HEIs) grew by 19% between 1994-95 and 2000-01, from 695,434 to 825,341 places (HEFCE, 2001a). However, cumulative enrolments fell short by 21,982 and in the last academic year (2000-01) alone some 14,465 funded places remained unfilled (see figure 3). The post-1992 ('new') universities² have experienced the most difficulty in maintaining current recruitment levels (The Times, 2001). This has created major funding problems, because many of them expanded during the 1980s to meet the general rise in student demand. Many universities currently experience difficulties in balancing their budgets (HEFCE, 2001b).

Participating in HE has become more expensive. Students contribute to the cost of university education through the payment of tuition fees and maintenance loans. Non-means tested maintenance loans were introduced in 1990/91 to partially replace means tested maintenance grants, although tuition remained free. Grants remained frozen until 1994/95 with a further shift to a loan element to replace grants. Tuition fees, set at £1000, further increased direct costs in 1998. Tuition fees are charged at a flat rate and students can be either fully or partially exempt. Students are eligible for either all or part of the maintenance loan, which is repaid after graduation at a zero real interest rate, subject to achieving a minimum salary. Tuition fees should not be seen as a major expense, when the overall costs of education are considered. Foregone earnings are a far bigger cost and the results will show that there was in fact little or no impact on applications. The major effect was on acceptances.

Figure 3 near here

The applications process

Approximately 400,000 applicants per annum apply to UCAS for undergraduate courses offered on behalf of 260 UK HEIs, covering around 42,000 separate courses. Postgraduate and part-time students apply to universities directly. The UCAS process is summarized in figure

² Post-1992 ('new') universities refer to those institutions that were granted university status following the removal of the divide between the former polytechnics and the pre-1992 ('old') universities.

4. The system is competitive and each applicant is allowed to make up to six applications (four in medicine), at the same or different institutions (usually by the beginning of January in the year they propose to go to university). So in what follows the difference between an applicant (one person) and an application (up to six per person) should be noted. The institutions then make offers, which can be either conditional (i.e. subject to achieving the entry requirements) or unconditional. Applicants make a first (firm) choice and second (insurance) choice. Applicants without any offers automatically enter the clearing process.

The majority of UK applicants receive conditional offers and only know whether they are accepted after receiving the results of their post-16 qualifications.³ They may be accepted by either their firm or insurance offers. However, applicants without any unconditional offers enter the clearing process, which runs from late August to early October. Institutions who have failed to achieve their target number of students advertise course vacancies and applicants contact institutions directly. Applicants can only accept one of the clearing offers they receive, after which they leave the admissions system. Overall, 76.7% of UK applicants were successful over the period 1996-2000.

Figure 4 near here

Market Trends

UCAS publishes a data set (see www.ucas.ac.uk) on applications and acceptances to courses offered by the HEIs who are members. The focus is on the leading 97 UK universities for which a measure of quality is available, and those applicants classified as UK domiciled, which account for 75.5% of all applications made through UCAS and 74.5% of acceptances, from 1996-2000.

³ The majority are Advanced (A) levels, Scottish Highers or the General National Vocational Qualification (GNVQ) Advanced. From September 2000, post-16 qualifications are assessed over two years. Entry requirements are converted into a UCAS tariff, whereby points are awarded for the qualifications and grades obtained. This change does not affect the data set, which ends at 1999-2000.

Table 1 ranks institutions according to the total number of applications and acceptances each receives.⁴ Many institutions experienced fluctuating demand, with applications rising from 1996-97 to 1997-98 and then falling between 1997-98 and 1998-99. Many applicants in the 1997-98 academic year may have decided not to postpone university entry (e.g. to take a gap year) to avoid paying tuition fees. 31 out of the 40 institutions experienced more than a 5% absolute change in applications between 1996 and 1999, and 35 institutions had more than a 5% absolute change in acceptances. 37 institutions experienced either higher growth in acceptances than applications or a smaller fall in acceptances compared to applications.

Among the highest 20 institutions for applications, 12 are pre-92 institutions whereas for acceptances 11 are post-92 institutions. The summary statistics suggest that, while the pre-92 sector receives more applications, the number of applications per institution is slightly higher among the post-92 sector. However, the number of acceptances per institution is far higher for the new universities. The most popular institutions in terms of applications tend to be located in the North of England and the Midlands. This is most likely explained by the relatively cheap cost of living in these regions. From the Greater London and South East regions, 8 institutions are among those with the lowest applications and 9 are among those with the lowest acceptances. These trends are indicative. A complete model of applications and acceptances is needed, which is discussed in the next section.

Table 1 near here

Table 2 ranks institutions by the growth in applications and acceptances they experienced between 1996-97 and 1999-00. 12 of the most improving institutions for applications are from the pre-92 sector, whereas 12 with the most improving growth in acceptances are post-92 universities. Brunel University has experienced significantly higher growth than others, which is partly explained by its 1995 merger with the West London Institute of Higher Education. 8 out of the highest 20 institutions experiencing the highest growth in applications and acceptances are located in Greater London and the South East.

⁴ The highest 20 and lowest 20 positions are presented. Complete tables are available at

Table 2 near here

University league tables often use the ratio of applications to acceptances as an indicator of the competition for places. This measure has weaknesses, notably it assumes that each institution achieves its target number of acceptances. Secondly, as the model of the next section makes clear, applications and acceptances are endogenous, dependent for example on entrance standards, so it is not apparent what the ratio of two endogenous variables actually means. Nevertheless, this measure is presented in table 3. Not surprisingly, 19 out of the highest 20 institutions are from the pre-92 sector. The only exception is Thames Valley University, which experienced an 87.3% rise in the ratio over the sample period. This outlier can be explained by a fall in acceptances (-43.0%) rather than a large increase in applications (only up 6.7%) from 1996-97 to 1999-00 (see table 1). Among those 20 institutions with the lowest application to acceptance ratio, 13 are post-92 institutions and many have experienced a fall in the level of their acceptances. Oxford and Cambridge universities also appear in the lowest 20. This result is peculiar to these two 'elite' institutions and demonstrates a self-selection effect, whereby only the brightest students who are confident of securing a place at these institutions consider applying. These two outliers also re-inforce the need for a formal model of applications and acceptances.

Table 3 near here

Table 4 presents total applications and acceptances by region. Greater London attracts the most applications and acceptances but also has the most institutions located within it. Relatively, the North West and Yorkshire & Humberside do well given the number of institutions located in these regions. 11 out of the 12 regions experienced a rise in applications between 1996-97 and 1997-98, prior to the introduction of tuition fees. Wales, the North West and the North East experienced significant reductions in applications between 1997-98 and 1998-99. Over the full sample period all regions experienced a rise in acceptances. Except for

the Eastern region, the growth in acceptances was greater than the rise in applications, a finding confirmed by the results presented in table 1.

Table 4 near here

Theoretical framework

Clearly, it would be a difficult task to model each detail of the complex decision process shown in figure 4, since little of what transpires will be recorded for analysis. There is information on the total applications - the basic demand input - and the final outcomes, namely the total acceptances to each educational institution and course

A three-equation model is proposed to model the acceptance and application process. This will consist of a demand equation (applications), a supply equation (acceptances) and a market clearing condition. The third endogenous variable in this three equation approach will be the realized average entry grade for the institution. In simple terms the idea is that an institution that wishes to expand, *ceteris paribus*, will be required to drop its entry standards. Similarly, raising entry standards can ration supply. Table 5 shows the average entry standards for the highest 20 and the lowest 20 institutions.

Table 5 near here

The demand for courses (AP_{it}) is defined as:

$$AP_{it} = f(P_{it-1}, Z_{it}) \quad (1)$$

The demand equation is specified for each institution i , where $i=1, \dots, 97$ and for the four years of entry $t=1,2,3,4$. AP_{it} is the number of places demanded for courses offered by institution i at time period t . P_{it-1} is the lagged entry standard of the institution (which might be thought of as roughly equivalent to the price variable in an elementary economics textbook exposition of the market supply and demand model). A good initial hypothesis is that applications should be responsive to entry grades (in lagged form), but whether this actually turns out to be the case is a moot point. The reason for this doubt reflects the institutional

structure of the admissions process. If applicants were limited to just one application, then the case for negative demand price elasticity would be clearer. There is a hierarchy of ability among applicants, and each has some idea of how well they are likely to do in their examinations. If there were just a 'one-shot' chance then only the most able and confident would apply for the hardest courses. A downward sloping demand equation might be expected in this case. But with up to six applications permitted and the fact that clearing offers a second chance, the picture is blurred somewhat.⁵

There may be a Veblen good effect. Courses with high entrance standards may attract more applications because of a 'prestige effect' and the Veblen good effect is more likely if applicants can make several applications, as is the case under the UCAS system. It is clear that admissions officers do to some extent engage in this complex problem of signalling quality. If the bid price is lowered this may actually reduce applications because this sends a signal of poor quality. It is also clear that institutions would quickly lose credibility if offer prices and market clearing prices were to diverge significantly.⁶ Against this, institutions with low entrance standards may attract additional applications because of the insurance choice effect. Thus the impact of entry grades on applications remains ambiguous. The justification for lagging this variable is that applications are made prior to the realized entry grade being known. Furthermore, advertised entry requirements are only indicative, many institutions will drop grade requirements during clearing.

Z_{it} is a vector of shift variables, which includes a quality ranking variable and dummy variables to represent pre- and post-92 universities, Oxbridge entry, year of entry and regions of the UK where each institution is located. The quality ranking variable is described in table 6 for the highest and lowest 20 institutions, and excludes entrance grades from the measure.

⁵ Leslie (2002) presents a theoretical model based on expected utility maximisation, which suggests that applicants will apply for courses with higher entry requirements if they have higher ability. The choice problem is that decisions must be made in advance of the grades being known for the typical applicant.

Table 6 near here

The position of an institution in published league tables may favourably influence the number of applications it receives. The 'new'/'old' university dummy allows for differences in the pattern of applications between the pre- and post-92 universities. Also Oxford and Cambridge universities appear to be special cases, in that that they receive comparatively fewer applications compared to other 'elite' institutions – there is a definite 'why bother to apply?' effect at work illustrated by well publicised rejection of candidates with highest A-levels but not apparently made of the 'right stuff'. Regional dummies are needed given the conclusions from table 3, suggesting that demand for places could be affected by the location of an institution within the UK. Year dummies account for time differences not otherwise explained, for example the impact of the introduction of tuition fees in 1998 as well as secular trends in HE popularity.

Supply (AC_{it}) is specified as:

$$AC_{it} = g(AP_{it}, P_{it}, X_{it}) \quad (2)$$

where P_{it} is the current entry standard and X_{it} is a vector of exogenous variables that influence supply. AP_{it} is included since the number of acceptances is conditional on the number of applications. Both P_{it} and X_{it} are instrumented, using the remaining exogenous variables in the system as instruments. and Included in X_{it} is the MASN for each institution, its total teaching funding per head and dummy variables for Oxbridge entry, pre-92 vs. post-92 institutions and the year of entry. The MASN is used for each institution since any change in the institution's recruitment target is likely to be reflected in a change in institutional acceptances. Higher teaching funding per head may act as an incentive for a university to accept more students. A dummy for Oxbridge is included. For many institutions beyond a certain level of acceptances the supply curve is effectively vertical. Consequently the price

⁶ However, Oxbridge, which has very high entry standards (see table 5), does not attract a disproportionate number of applications relative to acceptances (see table 3), so the Veblen good effect may be exaggerated.

will simply rise to whatever level is required to clear the market. In terms of the supply and demand model there is a short-run vertical supply schedule. If demand shifts to the right, all the adjustment takes place in a rising price, which then clears the market. There is, however, a maximum price and beyond that other ways of rationing are needed (interviewing etc) – table 5 suggests this maximum value effect for Oxbridge, which traditionally does a lot of pre-screening of applicants. Whether the institution is a ‘new’ or ‘old’ university is also likely to influence the level of acceptances (see tables 1 and 2). Dummy variables for the year of entry are also included.

In this model the realized average entry grade will adjust to clear the market. Institutions who fail to recruit enough students relative to target have the option of adjusting their entry requirements, whereas institutions that have popular courses will raise the entry standard to ration the available supply but this is subject to certain institutional constraints (discussed later). So grades are endogenous in the education model in the same way price is endogenous in the basic supply and demand framework. This is why the raw application/acceptance data of Table 3 has to be carefully interpreted because both variables are endogenous. The low application to acceptance ratio of Oxbridge is not symptomatic of failure – witness once again the high entrance standards of table 5.

The entry grade variable may not be freely flexible as the equivalent price variable in the simple supply and demand model; rather, there is probably a ratchet effect in operation. Typically courses/institutions will make bid prices or offer grades. Any applicant who reaches the prescribed grade is guaranteed a place. If a greater number than expected reaches the prescribed grade, the institution is obliged to increase the supply of places to meet the demand – there have only been very rare instances when institutions renege on offers. So there are difficulties in an institution making a short-run rise in its price to ration demand. What it can do is raise the bid price in future years. However, no such institutional constraint

is present on the downside to increase supply, other than a negative effect on the credibility of the institution. There is an upper but no lower bound constraint in the short run.⁷

Ideally institutions would wish to meet a set target (with a limited flexibility either way) without recourse to clearing. However, because of the obligation to meet demand at the offer price, there is strong pressure not to underbid the offer price. So the offer price is likely to be optimistic if anything. Clearing can actually be seen as a rational response to this institutional constraint. Nevertheless it is a fact of life that it is the less prestigious institutions that more readily use clearing to clear the market. The 2001/02 round suggests that universities are using clearing more frequently, which is squeezing the less prestigious institutions even more.

The educational model cannot, however, be completed by simply adding the equilibrium condition $AC_{it} = AP_{it}$ as in the simple supply and demand model. There are three reasons for this:

1. Applications are not synonymous with individuals, whereas acceptances are. Each applicant can make up to six applications. So, even in the absence of factors 2 and 3 considered below, market clearing would be associated with around six applications for each acceptance.
2. Not all applicants are accepted. Market clearing is not synonymous with each applicant being accepted, as in the supply and demand model. Should the approach be better termed as an excess demand model? Not necessarily, because in the supply and demand model, the demand variable is the *satisfied* demand. There would be less *satisfied* demand if the price rose. Here applications will include some whose demand will not be satisfied because they achieve a grade below the market clearing level for the particular course/institution that they are prepared to enter. Unlike the

⁷ But note the realized grade may rise even though all obligations are met because an unexpected number of entrants significantly exceed the offer price.

simple supply and demand model, this unsatisfied demand is included in the application data.

3. A more subtle reason is that the education model is more akin to a first-degree discriminating monopolist, rather than a competitive market. So even if factors 1 and 2 did not hold, there still would not be a simple market clearing condition. In the supply and demand model, there is one single universal price charged to all. In the education model, the market clearing price is a marginal price 'charged to' the lowest qualified candidate that clears the market. Non-marginal candidates will have grades at least as good as the marginal grade. Consequently the *average* grade (which is what is observed) will typically exceed the marginal grade that clears the market.

In summary, the third market clearing equation is a relationship between price, applications and acceptances, which must account for the above factors. No attempt will be made to estimate this third latent equation, but the discussion emphasises that applications and entry grades should be treated as endogenous in the acceptance equation. The applications equation can be estimated by OLS because it contains only one lagged dependent variable in the regressor list.

5. Estimation results

Equations (1) and (2) were estimated by pooling observations on the 97 UK universities over the four years of entry, where figure 5 summarises the variables used.⁸ A log-linear specification was adopted so coefficients give elasticities. In the applications equation, Greater London was the default region and 1996-97 the default time dummy.

Figure 5 near here

⁸ There were 387 observations because no entry grade data were available for SOAS in 1996.

The OLS estimation for the applications equation is presented in table 7. What it suggests is, first, that lagged entry grades have a significant positive effect on current applications. This suggests a Veblen good effect – in other words those institutions that recruit ‘more able’ students with higher A/AS points attract more applications. Applicants appear to be attracted to those institutions that require higher entry standards. This line of argument is supported by a significant and positive elasticity for the quality ranking variable, suggesting the higher up the ‘league table’ an institution appears the more applications it receives. The 0.117 coefficient implies around a 70% advantage between the best and lowest ranked institutions. The New/Old university dummy is significant and positive suggesting that on average post-92 universities achieve more applications. (Roughly a 56% advantage when the log point advantage of 0.45 is transformed as $1 - e^{-0.45}$.) While many of the post-92 institutions appear in the lower part of the quality ranking ‘league table’ (see table 6), this sector achieves slightly more applications per institution than the pre-92 sector (see table 1). However, whether this can be regarded as a reflection of success is a moot point because one reason why such places attract applications is for their ‘insurance’ effect. Many of these applications turn out to be ephemeral and are not translated into acceptances.

The Oxbridge dummy is significant and negative, as expected. There appear to be strong regional influences on applications with the dummy coefficients being significant in all but two cases, the South East and Eastern regions. Scotland and Wales both have negative coefficients, relative to Greater London. The strongest positive regional impacts come from the institutions located in the East Midlands and the North West. Notice that the regional dummies are quite powerful, suggesting that location matters rather more than prestige in attracting applicants. Northern Ireland has a particularly strong impact, which may reflect a strong local demand. The year dummies do not have significant coefficients in any case – so the various doomsday predictions concerning the impact of tuition fees on applications are not readily apparent, at least at this early stage.

The instrumental variables estimation results of the acceptance equation are presented in table 8 (instruments used for prices and applications were lagged prices, regional dummies, quality ranking, MASN and Teaching Funding PER Head, Oxbridge, Newold and the time dummies). Surprisingly, current entry grades do not appear to have a significant impact on acceptances.⁹ Both the teaching funding per head and MASN variables are significant and positive. This suggests that the allocation of additional student places by the funding councils (i.e. a rise in the MASN) leads to the institution accepting more students onto its courses, while those institutions that are awarded higher teaching funding per head have an incentive to accept more students.

The MASN variable may be tracking some more complex dynamics alluded to in the theoretical discussion, but not directly tracked in the regression equation. Consider a university that 'over-recruits' and is obliged to meet an unexpectedly high demand at its offer grades – the case of the horizontal short-run supply schedule. It is probable that such success is rewarded in subsequent years by a higher MASN. It may be that these strong short-run effects dominate the entry grade variable and accounts for its insignificance.

The new/old university dummy is significant and positive, suggesting that the post-92 sector accepts more students, a finding supported by table 1. Oxbridge accepts fewer students. Only one dummy for the year of entry (1997-98) has a significant positive effect on acceptances. There are two possible reasons for this result. First, institutions were forward looking, in the sense they accepted more applicants in the year before tuition fees/maintenance loans were introduced to ensure recruitment was maximized, expecting a fall in applications the year after. Secondly, applicants avoided gap years to avoid the costs of going to university and some applicants would accept second choices, rather than sitting out a year to improve their qualifications.

Tables 7 & 8 near here

⁹ A random effects panel data model was also estimated, but this also revealed little success with a

Concluding Comments

A number of conclusions can be drawn from this investigation of the changing pattern of applications and acceptances to UK universities. First, many institutions have experienced uncertain demand for their 'products', with fluctuating applications and acceptances. Established patterns were disrupted by the introduction of tuition fees in 1998. While some institutions suffered a fall in applications, demand recovered in the last year of the sample. The main impact of tuition fees appears to have been a fall in the overall application/acceptance ratio from 6.67 to 6.27 in 1997/98, and tables 7 and 8 suggest that this fall was mainly being driven from the acceptance side. Acceptances have grown at a faster rate than applications. For the full sample of universities, applications grew by 0.34% from 1996 to 1999, but acceptances increased by 10.16%. Universities appear to have overestimated the negative demand side impact of tuition fees and perhaps there was a somewhat panic stricken over-reaction.

A number of further factors may have added to the tuition fee effect on acceptances. First, institutions have become less selective in the face of limited growth in applications but with a need to maximize acceptances to maintain funding. Secondly, more applicants are achieving their conditional offer(s) - with a process of grade inflation operative in the face of little change in entry standards. It is clear that factors specific to a given institution play an important role in determining the level of applications and acceptances. Specifically, the ranking (prestige) of an institution, its location in the UK and whether it is a pre-92 university or former polytechnic are all important factors. There is a well-defined Oxbridge effect, which discourages applications except from those who might be expected to achieve the highest qualifications.

So what does this work suggest about the possibility of increasing participation in HE to meet government targets of a 50% participation overall in HE? The large rise in demand for HE

experienced in the 1980s is unlikely to be replicated in the future, as traditional sources of student supply have been exhausted. Indeed, the 2001/02 round strongly suggests that universities are meeting target numbers by increasing the proportion accepted of those who apply. The question is if the quality of provision can be maintained in the face of these trends, or whether a substitution towards a well-defined two-tier system with an increasing proportion of HND/Foundation course type provision is necessary. If applications are to be increased, recruitment strategies must aim to widen access to HE to applicants among currently under-represented groups.

UK Acceptances	Total UK acceptances by institution, 1996-97 to 1999-00. Source: UCAS.
Entry grades	Average A-level/ AS level points achieved by students on entry to each institution, 1996-97 to 1999-00. Source: Times Higher Education Supplement (THES)., www.thesis.co.uk.
Lagged Entry Grades	Average A-level/ AS level points achieved by students on entry to each institution , 1995-96 to 1998-99. Source: THES
Quality ranking	<p>Quality ranking of institutions based on information published by the THES on</p> <ol style="list-style-type: none"> 1. average teaching quality score; 2. average RAE score; 3. student-staff ratio; 4. graduate destinations (in terms of the proportion of graduates in work or further study 6 months after graduation) 5. The proportion of firsts and upper-second class degrees awarded by the institution. <p>Each component was ranked and then an overall rank computed with weights of 2.5 for teaching and 2 for research. This methodology follows that used in the Sunday Times League Table 2001.</p>
Newold	Dummy variable, which equals 1 if the institution is post-92 institution and 0 if the institution is pre-92.
Oxbridge	Dummy variable, which equals 1 if the institution is either Oxford or Cambridge university and 0 otherwise.
Regional dummies	Equals 1 if the institution is located in the classified region and 0 otherwise.
Year dummies	Equals 1 for the year of application and 0 otherwise.
MASN	Maximum Aggregate Student Number for each institution. Obtained from information published by HEFCE and the Scottish, Welsh and Northern Ireland Higher Education Funding Councils.
TFPH	A proxy for total teaching funding per head defined as total teaching funding divided by the MASN for each institution. Source: HEFCE and the Scottish, Welsh and Northern Ireland Higher Education Funding Councils.

96	University of Teesside	5	5	4	2
97	Thames Valley University	2	2	3	1

Notes: The quality rankings were obtained from raw data published on each institution's average TQA score; average RAE score; graduate destinations; proportion of firsts and 2:1s and student-staff ratio/ TQA scores were given a weight of 2.5 and research a weighting of 2. Data ranked on the basis of the 1999 figures.

Table 7: OLS estimation results- application equation		Number of observations = 387 F(18, 368) = 29.52 R-squared = 0.34
