8 Keywords: Microbiology, Education

1 Microbiology has a century-long tradition of commitment to science education [1], relying heavily on  
2 practical activity in its teaching. Since the introduction of the National Curriculum in the United  
3 Kingdom 1988, the content of microbiology in schools has undergone some changes and additions.  
4 For example, the Education Act 1996 highlighted the need for education on HIV/AIDS and sexually  
5 transmitted infection, with a more recent push to include PCR. Despite this, practical activity in  
6 schools is in decline for a variety of reasons (cost, time, curriculum issues, class size etc.) [2]. Some  
7 have even suggested that microbiology as a subject is undergoing a change in direction, from the  
8 'classical' techniques to a more molecular focus, and is potentially losing its identity as an individual  
9 science [3, 4].

10 A recent report [5] found that among the activities that encouraged/discouraged students from  
11 school science, the opportunity to conduct experiments, and a chance to learn subjects relevant to  
12 the real world as well as science aiding future study/career options were positive motivators. An  
13 increase in young students interested in any subject will hopefully result in an increased number of  
14 researchers and other professionals in years to come. Thus microbiologists of today should play a  
15 role in the promotion of their subject in order to maintain its health for the future [6].

16 There is little evidence available that reveals the extent to which practical microbiology is being  
17 performed in schools, and the issues, if any, that prevent teachers from delivering practical  
18 microbiology. Thus, a questionnaire-based survey was circulated to over 700 teachers (teaching ages  
19 11 to 18) in the UK, receiving 248 responses. The survey focused on three areas:

- 20 • Were teachers carrying out practical microbiology activities in schools?
- 21 • What were the perceived limitations in delivering practical microbiology?
- 22 • To what extent was practical activity valued in teaching microbiology?

23 It was hoped that results would indicate how practicing microbiologists could help to ensure that  
24 microbiology in schools remained relevant, stimulating – and indeed present at all. The majority of  
25 respondents (77%) considered science practical activity in the classroom extremely valuable and 67%  
26 of respondents also found practical activity valuable in the teaching of microbiology. Practical  
27 microbiology was utilised by 65.7% of teachers. The activities cover a variety of different topics  
28 (n=37), ranging in subject and skill level. Five activities mentioned were not microbiology  
29 (investigating animal cells, plant cells, blood smears, DNA extraction from fruit, and cloning  
30 cauliflower). The relevant activities addressed a range of principles of microbiology, biology, and  
31 science in general (Figure 1). The majority of activities mentioned used bacteria. However, 10.2%  
32 used yeast or fungi, with a small number using algae and bacteriophage (1.5% and 0.5% of activities

1 respectively). It was heartening to note a significant presence of microbiology in the school  
2 laboratory.

3 All respondents stated that they faced at least one limitation to delivering practical microbiology in  
4 the classroom (Figure 2). Equipment was the most frequently cited limitation (47.6%), followed  
5 closely by financial constraint (41.5%). An autoclave and an incubator were considered essential for  
6 microbiology practical activity. Both of these items are 'benchmarks' for the science laboratory in  
7 secondary schools [9]; nevertheless alternatives can be found (pressure cooker and room  
8 temperature incubation). A recent survey [10] on resourcing practical science at secondary level  
9 provides further evidence that teachers have widespread problems with equipment and finance. It  
10 found biology to be the poorest resourced science taught in English secondary schools (particularly  
11 insufficient quantities of working equipment available to perform effective practical work).

12 Data from our survey suggest significant differences between those teaching 11-14 (n=191) & 14-16  
13 (n=202) and 16+ science/biology (n=144). Although the latter find finance as a limitation, they  
14 continue to deliver practical microbiology nevertheless (Teachers not carrying out these activities did  
15 not consider finance to be a limitation). Those teaching 16+ did not suggest finance as a limitation,  
16 but instead highlighted a number of other issues which included confidence in technique,  
17 equipment, technical support and health and safety concerns. The activities carried out at 16+  
18 education were of a higher skill level (for example using plant extracts to investigate antimicrobial  
19 action and PCR), compared to 11-16, where the activities were predominantly 'classic' in nature,  
20 with a lower level of skill (for example culturing on agar and practicing aseptic technique). These  
21 findings suggest that there is a recognition that more expertise is required for higher level delivery.

22 The Society for General Microbiology (SGM) is one of the largest learned societies promoting  
23 microbiology. It provides significant support to teachers in microbiology education via a school  
24 membership scheme. The survey investigated whether school membership affected delivery of  
25 practical microbiology. The data suggest that non-members of SGM were significantly more likely  
26 ( $P < 0.05$ ) to find equipment, technician support and reliability/reproducibility a barrier to their use  
27 microbiology, compared to members. This finding clearly demonstrates the value of appropriate  
28 professional support for the delivery of microbiology in schools

29 Overall, although the educational benefit of practical microbiology was acknowledged throughout  
30 the survey, many teachers encounter difficulties with relevance to the curriculum, and deliverability.  
31 Results of the survey indicate that teachers hold certain misconceptions about the excessive cost,  
32 technical difficulty, reproducibility/reliability and health and safety aspects of performing

1 microbiology in the classroom. All of these limitations can be addressed by using trusted and tested  
2 practical resources, and by following the advice given by professional bodies and organisations that  
3 endeavour to aid teachers in improving practical science in the classroom.

4 In a 'free text' section of the survey, teachers noted that although students enjoyed the subject of  
5 microbiology as a whole "the National Curriculum (NC) chokes creativity" (one comment), with  
6 another teacher suggesting the NC does not provide the time for practical microbiology, possibly  
7 restricting student's interaction with the science. However, such views are ill-founded: microbiology  
8 is well represented in the National Curriculum and teaching specifications [11]. In addition,  
9 microbiology offers a range of opportunities for teachers to utilise microorganisms to demonstrate  
10 other phenomena, for instance, using algae to demonstrate photosynthesis and the effects of  
11 pollutants, or yeast to demonstrate gas cycling [12].

12 Thus, there are two audiences keen to increase their encounters with practical microbiology –  
13 teachers and students. One way to address this need is to provide effective two-way communication  
14 between subject 'experts' and teachers. It is important that teachers (especially those who may not  
15 be biology/microbiology specialists) are encouraged to utilise microbiology in the laboratory.  
16 Professional practicing scientists, who understand the subject, should be able to provide this  
17 support. The Reward for their efforts should also be significant. By getting involved in the  
18 development of inspirational school practical science which illustrates concepts required by the NC;  
19 troubleshooting when problems are encountered, , and ensuring relevance and impact to the world  
20 at large the number of students who become interested in the field should increase. Hopefully, this  
21 will result in more microbiologists and researchers in years to come. Thus, professional  
22 microbiologists should be prepared to play a greater role in the promotion and delivery of their  
23 subject in schools in order to maintain its health for the future.
