#### Abstract.

**BACKGROUND:** Although low back pain (LBP) is a debilitating problem internationally, there is not a lot of research on its impact on physical, psychosocial and lifestyle factors. Especially in Mediterranean countries, such as Greece, it is not sufficiently explored whether physical (pain location, activity limitation etc.), sociodemographic (education, smoking etc.) or lifestyle factors (i.e. quality of life or anxiety) are influenced by LBP.

**OBJECTIVE:** To estimate LBP prevalence in the Greek general population and explore its association with particular sociodemographic, physical and lifestyle factors.

**METHOD:** A sample of 3125 people of the Greek adult population was randomly selected by stratified sampling encompassing rural and urban representation within the Greek mainland. An extended survey form was developed entailing three sections; personal (sociodemographic) information, questions on symptomatology and physical factors (i.e. pain characteristics, recurrence, physical disability etc.) and 3 self-administered questionnaires (including mostly lifestyle factors); Hospital Anxiety and Depression (HAD) scale for anxiety and depression, SF-12 for quality of life (QoL) and Roland-Morris for disability.

**RESULTS:** A total of 471 (15%) people reported LBP (210 males, mean age: 47.04  $\pm$  15.03). Amongst them 60% reported sciatica, 76% suffered recurrent LBP and 70% received specialist care. Low disability levels, moderate to high pain intensity, gender differences and good self-reported QoL and psychosocial status were reported. Sociodemographic characteristics (income, smoking, marital status etc.) were not associated with LBP physical factors, apart from age which correlated with physical disability and wellness (r being 0.446 and 0.405, respectively, p < 0.001). Physical factors (particularly pain intensity and location) correlated with lifestyle factors (QoL) and disability (r ranging between 0.396 and 0.543, p < 0.001). Mental wellness, anxiety and depression (as lifestyle factors) were not associated with sociodemographic or physical factors.

**CONCLUSIONS:** Physical parameters were amongst the most prevalent characteristics of the Greek sample, thus offering a direction towards a more targeted treatment and rehabilitation planning. Unlike previous literature, most sociodemographic characteristics were not correlated with any LBP physical or lifestyle factors, thus possibly indicating a different socioeconomic background and aetiology domain to that of the usual non-specific LBP spectrum.

Keywords: Low back pain, prevalence, physical, sociodemographic, lifestyle, Greece

#### 1 1. Introduction

Low back pain is one of the commonest muscu-2 loskeletal entities, notorious in causing physical, eco-3 nomic, functional, psychosocial, behavioural and life-4 style problems. It is suggested to affect up to 60–80% 5 of the general adult population at some point in their 6 lifetime [1–4]. High prevalence rates are internation-7 ally widespread [3,5–7], from the most developed parts 8 of the world, including US [8,9], North America [5], 9 10 Australia [2], Great Britain [10,11] and other European countries [11–16], to developing ones [17,18], such as 11 Pakistan [19], Turkey [20] and Nigeria [21,22]. 12

LBP appears to be a highly prevalent problem 13 within Greece, too. It is considered ninth in the list 14 of the most common reasons requiring hospital ad-15 mission [23] and first in the list of orthopaedic con-16 ditions being encountered in an emergency depart-17 ment [24]. It also seems to be the most common 18 musculoskeletal problem amongst the Greek popula-19 tion [25]. In an extensive cross-sectional study across 20 Greece, a group of rheumatologists investigated the 21 prevalence of rheumatic diseases, and found that the 22 most common one was LBP, with a point prevalence 23 of 11% [25]. Stranjalis et al. [15] in a cross-sectional 24 study encompassing mainly urban population, found 25 a one-month prevalence rate of 32%. A more recent 26 smaller-scale study investigated the annual prevalence 27 patterns of musculoskeletal diseases in rural primary 28 care settings in Crete, the largest Greek island [26]. 29 LBP presented with the highest prevalence rate of ap-30 proximately 57% amongst the various musculoskele-31 tal conditions studied. A more recent study within 32 an urban setting reported 40% LBP and 25% sciat-33 ica [27]. Some other epidemiological studies have also 34 investigated occupational LBP in Greece, in nursing 35 staff [28], shipyard employees [29], dentists [30], pub-36 lic office workers [31], all of which reported high 37 prevalence rates. 38

In terms of reported physical factors, such as pain 39 intensity and location, disability, chronicity, informa-40 tion on symptoms, work absence and care-seeking or 41 other lifestyle parameters, such as quality of life or 42 psychosocial impact, there is scarcity of relevant re-43 search within the Greek setting. Spyropoulos et al. [31] 44 reported an 11% of his affected population (public of-45 fice workers) suffering from severe LBP, 43% of which 46 suffered from recurrent episodes. Within the occupa-47 tional studies, work absence ranged between 10% and 48 30% [28–30] whereas, Stranjalis et al. [15] reported 49 a sick leave rate of 19% amongst the general popula-50

tion with a mean duration of 5 days off work. In terms of healthcare utilisation, approximately 30% of the affected LBP samples consulted a physician doctor or a general practitioner for their symptoms [15,26].

From the above, it is evident that in Greece, LBP is a debilitating problem, however, there is not a lot of available research on its impact on physical factors, such as pain parameters and physical disability, or on lifestyle factors, such as quality of life (QoL) and other psychosocial parameters. Furthermore, as LBP is acknowledged as a health problem with not only biomedical, but also social, psychological, economic and functional consequences, it is important to explore how several sociodemographic (i.e. marital status, smoking, education etc.) and lifestyle factors (i.e. anxiety or physical quality of life) within the Greek setting are influenced by LBP.

Given the above, the aims of the present study were to estimate LBP prevalence in a Greek general population sample and explore its association with several physical, sociodemographic and lifestyle factors.

#### 2. Methods

#### 2.1. Sample

The sample included Greek citizens over the age of 16, which were selected by multistage sampling with definition of the sample quotas based on sex, and geographical type of residence (urban, semi-urban, rural), according to the results of the 2011 National Census of the Hellenic Statistical Authority (ELSTAT), the Greek official statistical authority. The geographical area covered included central and western Greece, and according to the 2011 National Census, urban representation corresponded to cities with more than 10.000 inhabitants, semi-urban to towns with population between 2000 and 10000 people, and rural areas corresponded to villages with less than 2000 inhabitants. In order to obtain a representative sample of Greek citizens, the sample was stratified according to geographical location, to obtain as greatest representation as possible. For the geographical location, central and western Greek mainland was divided into 5 urban areas, encompassing 2 large (Athens, Patras), 2 medium sized (Ioannina, Trikala) and one smaller city (Korinthos). In addition, 20 rural areas (10 towns and 10 villages) surrounding each selected city except for Athens were picked up for the study.

The survey was conducted and administered by 8 physiotherapists, well trained in this questionnaire ad-

ministration procedure, who attended a full-day training by the principal investigator (EB) on interview administration utilising the presenting assessment form.
The study was approved by the Scientific Committee of the Technological Educational Institute (TEI) of Western Greece (former TEI of Patras).

#### 105 2.2. Survey development

An extended survey form based on current litera-106 ture was developed. The survey form which was devel-107 oped (Greek survey) was self-reported including per-108 sonal (sociodempgraphic) information (age, education, 109 marital status, annual income, smoking history etc.) 110 and 18 questions on physical features, that is, symp-111 toms, functionality and LBP-associated history (recur-112 rence, treatment, other musculoskeletal etc.), which ac-113 cording to the literature have been found to be strongly 114 associated with LBP [3,4,15,32]. The majority of the 115 questions were taken from an assessment sheet (Greek 116 proforma), which has previously been tested for its re-117 liability and has already been utilised among Greek 118 LBP samples [33,34]. Questions on symptoms in-119 cluded pain areas by numbered areas on a body chart), 120 pain intensity on a visual analogue scale (VAS) being 121 reported on three levels; average pain (i.e. what is their 122 pain on average), pain at its 'worst' (i.e. what is their 123 maximum amount of pain) and pain at its 'best' (what 124 is the minimal amount of pain they have), reported sci-125 atica, frequency, etc. LBP was reported if the partici-126 pant suffered during the past 7 days (including the day 127 of the survey) [35] and pain was located in the lumbar 128 (low back) region. 129

In addition, three reliable, validate and extensively 130 used self-administered questionnaires were added in 131 the Greek survey form: i) The Roland-Morris Disabil-132 ity Questionnaire, which is one of the most popular 133 questionnaires (entailing 24 questions), assessing mild 134 to moderate physical disability caused by LBP, ii) Tthe 135 Hospital Anxiety and Depression (HAD) scale, which 136 is a 14-item scale detecting anxiety (7 items) and de-137 pression (7 items) in people with physical health prob-138 lems, and finally iii), the SF-12 Health Survey, of-139 ten reported as a QoL measure. It is a shorter version 140 of the SF-36 Health Survey (version 2), entailing 12 141 questions for measuring physical health and well-being 142 (mental health). All three questionnaires have previ-143 ously been cross-culturally validated within the Greek 144 setting and have been utilised across similar popula-145 tions [34,36–38]. 146

Prior to being administered, the survey form was piloted in a LBP sample of 30 people, for clarity and comprehensiveness. Following this, some minor corrections based on the pilot sample feedback were undertaken.

#### 2.3. Procedure undertaken

For each of the 25 testing sites in total, the 'start-153 ing point zero', corresponded to the biggest (and most 154 popular) square of the town, city or village; which usu-155 ally constitutes the buzziest location in the Greek set-156 tings. From this zero point, each tester was directed to-157 wards an eastern and northern direction and included 158 in the study every third household/building situated on 159 the right side of the central road (number 3 was a ran-160 domly selected number). Testers were instructed to ask 161 each subject a standardised question in order to iden-162 tify if they suffered LBP. Age and sex of people who 163 did not suffer from LBP were reported whereas, people 164 who suffered LBP were provided a full informed con-165 sent prior to their participation in the study. In cases 166 where there was no answer from a given household 167 (i.e. people were absent), interviewers would visit for 168 a second time (evening time). When each tester would 169 reach the end of road or the border of the given city, 170 town or village, he was instructed to return to the cen-171 tral square again following a parallel road or avenue 172 and start again surveying by using a 5-point star-type 173 clockwise route. The study was carried out between 174 October and November 2012. 175

### 2.4. Data analysis

Prevalence was estimated descriptively by frequen-177 cies and percentages, whereas, LBP factors (sociode-178 mographic, physical and lifestyle data) were also es-179 timated descriptively (means and standard deviations 180 for interval/ratio data and percentages and frequen-181 cies for nominal/ordinal type data). The association of 182 LBP features with several sociodemographic, physi-183 cal and lifestyle parameters was tested using  $\chi^2$ , in-184 dependent sample t tests and Pearson's correlation co-185 efficient. Regression analysis was carried out using 186 two linear regression analysis models with two depen-187 dent variables for predicting associations; i) pain in-188 tensity (based on the worst pain intensity on the VAS) 189 and ii) disability (based on the Roland-Morris Disabil-190 ity Questionnaire). Analysis was performed utilising 191 SPSS (Version 20.0). 192

3. Results 193

Out of 3125 people being questioned, a total of 471 194 (15%) reported LBP (210 males, 261 females, mean 195 age:  $47,04 \pm 15,03$ ) at the time of the survey. Table 1 196 summarises the sample's distribution according to ge-197 ographical area. Amongst them, nearly 76% were suf-198 fering from recurrent LBP, 60% reported associated leg 199 pain (sciatica), and 70% received specialist care and 200 were already under some form of conservative treat-201 ment. Their average and worst pain intensity on a VAS 202 score was  $5.26 \pm 1.8$  and  $7.99 \pm 1.8$ , respectively. 61%203 reported that their LBP was limiting their activities and 204 function. Table 2 summarises the sample's sociodemo-205 graphic, physical & lifestyle characteristics. 206

Table 3 presents the results of linear regression anal-207 ysis using two different dependent variables; pain in-208 tensity (VAS at worst) and disability (Roland-Morris), 209 keeping as independent variables the samples's so-210 ciodemographic, physical and lifestyle characteristics. 211 Significant regression equations were found for pain 212 intensity<sup>1</sup> and disability.<sup>2</sup> Pain intensity was associated 213 with age from the sociodemographic factors, bed rest, 214 activity limitation due to LBP and specialist visit from 215 the physical factors, and anxiety and mental health 216 from the lifestyle factors. Disability was associated 217 with sex and age (sociodemographic), activity limita-218 tion due to sciatica, bed rest, pain intensity and fre-219 quency from the physical factors, and physical well-220 ness (lifestyle factor). 221

Table 4 presents associations (correlations) with so-222 ciodemographic, physical and lifestyle factors across 223 the sample. Sociodemographic characteristics (income, 224 smoking, marital status etc.) did not yield signifi-225 cant associations, apart from age which correlated 226 with disability (physical factor) and physical wellness 227 (lifestyle factor), (r being 0.446 and -0.405, respec-228 tively, with p < 0.001). Significant associations were 229 yielded between pain intensity with disability (as phys-230 ical factors) and QoL (SF-12 physical subscale as a 231 lifestyle factor), (r being 0.543 and -0.453, respec-232 tively with p < 0.001). Below knee pain was asso-233 ciated only with activity limitation (r = 0.453). The 234 other lifestyle factors (anxiety, depression and mental 235 wellness) had only weak associations with age, educa-236 tion and pain intensity; r ranging between 0.301 and 237  $(0.342 \ (p < 0.001))$ . Whereas, visit to specialist had 238 weak associations with high disability and QoL (r be-239 tween 0.327 and 0.379, p < 0.001). 240

 ${}^{1}[F_{(22,448)} = 41.245, p < 0.001$ , with an R<sup>2</sup> of 0.669].  ${}^{2}[F_{(4,466)} = 19.441, p < 0.001$ , with an R<sup>2</sup> of 0.143].

In terms of gender, although men and women 241 had comparable ages (men-mean age 45.29  $\pm$  14.9, 242 women-mean age:  $48.45 \pm 15.0$ ), significant differ-243 ences amongst them were reported on several sociode-244 mographic (education, marital status, smoking, annul 245 income), physical (sciatica and its functionality, pain 246 intensity, specialist visit, other musculoskeletal prob-247 lems) and lifestyle factors (anxiety and depression 248 and metal health). LBP recurrence, disability, bed rest, 249 treatment, LBP functionality and physical health did 250 not reveal statistically significant gender differences. 251 Table 5 summarises gender-adjusted prevalence distri-252 butions of sociodemographic, physical and lifestyle pa-253 rameters. 254

#### 4. Discussion

The present study aimed to explore the association 256 of sociodemographic, physical and lifestyle factors on 257 LBP in a general population sample of central and western Greece. It was within the scope of the study to attempt to use a representative sample of the general population, encompassing a combination of rural and 261 urban representations. The combination of the 5 cities with variable sizes across central and western mainland and the selection of two towns and villages sur-264 rounding each city was thought to be an objective way of capturing a general population sample.

#### 4.1. Prevalence

The prevalence of LBP (15%) found in the present 268 study is in agreement with an older systematic review 269 by Walker [6] on LBP point prevalence (ranging be-270 tween 12–33%), as well as a more recent systematic 271 review by Hoy et al. [7] on the global prevalence of 272 LBP, which showed the point prevalence of activity-273 limiting LBP was estimated to be  $12 \pm 2\%$ , and the 274 1-month prevalence was estimated to be  $23 \pm 2.9\%$ . 275 However, a number of epidemiological studies have 276 yielded higher prevalence rates in developing (56% in 277 Qatar [39], 32% in Africa [18], 34% in Tibet [40]) and 278 developed countries (19% [41] and 15-22% [11] in UK 279 with a trend of an increased prevalence over time [42], 280 26% in Australia [2], 26,9% in the Netherlands [14], 281 29% in Canada [43], and between 32% and 48% in 282 Germany [11,35]). 283

Similar to international studies, previous Greek 284 studies have yielded considerable variability in preva-285 lence rates. Point prevalence range between 11% in a 286

E. Billis et al. / Association of low back pain on physical, sociodemographic and lifestyle factors

\*For independent sample's t test, \*\*For  $\chi^2$  test.

large scale study encompassing rural and urban repre-287 sentation from 8547 people [25] to 57% from a smaller 288 scale study in primary care conducted in a rural part 289 of Greece [26]. Two urban based studies reported 1-290 month and 6-month prevalence rates of 31% [15] and 291 40% [27], respectively. Whereas, occupational LBP 292 prevalence rates are somewhat higher, too, ranging 293 from 37-38% in public office workers [31] and ship-294 yards [30] to 46% in dentists [29] and 75% in Greek 295 nursing personnel [28]. What is interesting in the pre-296 senting study is the variability in prevalence rates 297 across the 5 urban testing sites (ranging from 7% to 298 25%). The reason for this low prevalence in the area of 299 Athens is not known, although within-country fluctu-300 ations have been reported in previous studies [11,20]. 301

Future studies should further explore LBP point prevalence around Athens.

This variability across the present study and previous ones apart from differences in the methodologi-305 cal design, such as differences in the sample size, ap-306 plication of randomization as opposed to convenience 307 sampling methods in a number of other studies, utiliza-308 tion of rural versus urban versus mixed populations etc. 309 could also be attributed to differences in the definition 310 of LBP. Whereas, a number of studies have either not 311 clearly defined how they were reporting LBP in their 312 study [13,25] or used the one day limit for LBP and 313 utilized a location of pain between the last ribs and the 314 gluteal folds [2,7,44], the presenting study utilized a 7-315 day limit for LBP and location of pain was restricted 316 to the lumbar (low back) region only. Defining dura-317

tion for point prevalence and location of pain in LBP 318 epidemiological studies has been a subject of great de-319 bate in the past [44–46]. In this study, the presenting 320 pain location was selected in order to distinguish true 321 back pain from other referred pain (i.e. back-associated 322 leg pain, gluteal pain etc.). Anatomical referral pain 323 patterns were already recorded in the survey. The 7day duration has been used in previous epidemiolog-325 ical studies [35,47] and was also thought to be more 326 'realistic' in terms of true 'bothersomeness'; it was 327 felt that a longer day duration would better distinguish 328 LBP from any incidental ache experienced. Thus, this 329 definition of duration and location in the present study 330 could partly explain the differences in the lower point 331 prevalence rates between this and other epidemiologi-332 cal reports. However, further work should take place in 333 this area in order to confirm this. 334

#### 4.2. Physical factors 335

Regarding self-reported leg-associated back pain, 336 60% of the LBP sample reported sciatica and 40% re-337 ported having below knee pain. Although these num-338 bers are comparable with previous studies, both inter-339 nationally [41–48] and in Greece [15], there is large 340 variability in self-reported sciatica [27,49]. Again, this 341 could be attributed to the lack of a gold and reporting 342 sciatica [50]. Pain below the knee in this study has also 343 been associated with activity limitation, indicating re-344 stricted functionality with below knee pain (Table 4), 345 thus, justifying Hider et al.'s [48] recent distinction be-346 tween below and above knee sciatica. 347

Over two thirds of the sample (76%) were suffering 348 from recurrent LBP episodes and over half of the sam-349 ple (54%) had LBP most of the days. 70% received 350 specialist care and were already under some form of conservative treatment whereas, nearly a third of them 352 (27%) underwent bed rest for up to a week. Although 353 most of these rates are comparable with several other 354 studies regarding pain frequency, recurrence and bed 355 rest [15,51], it is interesting to note the high percent-356 age of the sample receiving specialist care (secondary 357 care). This number is much higher than most stud-358 ies investigating healthcare seeking (primary or sec-359 ondary) patterns [48,51–53]. This percentage is how-360 ever comparable with a Greek study by Korovessis et 361 al. [27] and is in agreement with previous report re-362 garding healthcare utilisation within Greece [54–56]. It 363 could therefore be suggested that within Greece there 364 is an overwhelming percentage of healthcare utilisa-365 tion amongst LBP patients. It would be interesting to 366

follow through this sample and perhaps further explore their natural course and the medical options offered to them

Despite the high percentage of people seeking med-370 ical care, the sample presented with mild to moder-371 ate disability, as indicated by the Roland-Morris. Sig-372 nificant associations were yielded between below knee 373 pain with disability and QoL (SF-12 physical sub-374 scale only), indicating more severe disability deficits 375 with radiating pain. However, their 'worst' pain inten-376 sity was high and 61% reported that their LBP was 377 limiting their activities and function. This moderate 378 intensity-low disability amongst the LBP sample is 379 quite common in several studies [2,11,41,43]. Further-380 more, disability has yielded moderate to strong associ-381 ations with pain intensity and age (the older the people 382 the higher the reported disability). Such associations 383 are also familiar in other studies [57]. Disability was 384 also found on the regression model to be suggestive of 385 age (from the sociodemographic factors), bed rest, pain 386 intensity, sciatica limited activity, pain status and fre-387 quency (from the other physical factors) and physical 388 health (on SF-12 physical subscale) from the lifestyle 389 factors. 390

More severe functional limitations with sciatica and 391 more extensive pain were noted amongst women, es-392 pecially for those with reported sciatica and its func-393 tionality. Amongst other physical factors, women re-394 ported higher pain frequency & intensity, more vis-395 its to specialists and other musculoskeletal problems 396 (i.e. neck pain). Women also reported higher ratings 397 on lifestyle factors, more anxiety and depression and 398 poorer self-reported mental wellness (than men). Such 399 findings are in line with previous research indicating 400 a more 'severe' physical and lifestyle impact of LBP 401 amongst women, for which causal relationship is un-402 clear [3,4,27,35]. However, in view of the differences 403 in methodologies across studies, conclusions or gener-404 alisations cannot be made. Interestingly, a number of 405 factors, LBP recurrence, self-reported disability, bed 406 rest, treatment, and self-reported physical health did not reveal statistically significant gender differences.

### 4.3. Sociodemographic factors

As regards to the sociodemographic factors, the regression analysis model did not reveal any associations of inhabitancy area, marital status, education, income or smoking history with either disability or pain intensity. Sex has been associated with physical disability and age has been the only factor associated

8

407 408

411

412

413

414

with both, pain intensity and disability on the linear 416 regression models. Age was also correlated with self-417 reported disability (as a physical factor) and QoL (as 418 a lifestyle factor), which has been found to be the 419 case in most LBP epidemiological studies [4]. Correla-420 tions of the remaining sociodemographic factors with 421 other physical (disability, physical limitations, pain lo-422 cation) and lifestyle factors (mental wellness, anxi-423 ety, depression) were also weak,. Interestingly, this 424 contrasts previous research findings, which support 425 stronger associations with similar sociodemographic 426 parameters [3,20,58,59]. Further research on a more 427 extensive list of sociodemographic features would be 428 of interest to explore. 429

#### 430 4.4. Lifestyle factors

Anxiety and depression were low to moderate, with 431 a statistical significance difference amongst men and 432 women (women scoring higher in both scales). Weak 433 associations were yielded for both, anxiety and de-434 pression with sociodemographic and physical parame-435 ters. Anxiety was found predictive of pain intensity on 436 the regression model. Although anxiety and depression 437 have been suggested as risk factors for LBP in several 438 studies [64–67], strong associations were not found in 439 this study. It could be argued that the low disability-440 low severity profile of the sample could explain such 441 findings. 442

QoL as measured by the SF-12 Health Survey also 443 demonstrated a mildly affected profile with a more sig-444 nificant overlay amongst women in self-reported men-445 tal wellness. Stronger associations were yielded be-446 tween SF-12 physical subscale with one sociodemo-447 graphic and one physical factor; age and pain inten-448 sity, respectively. Physical and mental wellness were 449 predictive of disability and pain intensity, respectively. 450 This relatively good QoL picture of the sample has also 451 been reported amongst musculoskeletal conditions (in-452 cluding LBP) [26,38,68] and across general popula-453 tion samples [69]. This could partly be explained by 454 our low severity sample profile. It could also partly 455 be the result of a culturally-driven issue as indicated 456 in Antonopoulou et al.'s study [26]; they believe that, LBP is perceived as a low severity symptom (espe-458 cially amongst rural samples), and thus do not feel that 459 lifestyle is strongly affected by it. 460

It appears that *pain intensity* was one of the factors
which, in the present study was found to be associated with gender, age, bed rest, activity limitation due
to LBP, specialist visit, anxiety and self-reported men-

tal wellness. Significant correlations were also yielded 465 between pain intensity with disability and QoL, indi-466 cating strong associations between them. In this study 467 and, as opposed to previous studies, three levels of 468 pain intensity were measured; average pain, pain at its 469 worst and pain at its best. This three-level pain mea-470 sure was chosen in order to better 'capture' the im-471 pact of pain in demographic, physical and lifestyle 472 factors. Indeed, it was noted that pain at its worst 473 and to a lesser extent average pain intensity was the 474 most indicative pain factor. Pain intensity is probably 475 one of the most useful and commonly utilised LBP 476 outcome measures [60-62] without always consistent 477 findings [63]. Perhaps distinction and utilisation of a 478 multi-level pain intensity measure (as ours) could lead 479 to more accurate and consistent predictive findings. It 480 is therefore, suggested that future studies should en-481 compass, along with current pain, worst pain intensity 482 as an independent self-reported measure. 483

One of the major strengths of the current study is the sampling method; which was of a random nature, addressing a general population sample with both urban and rural representation in the Greek mainland, thus enhancing the study's external validity. We also tried to report a variety of sociodemographic, physical and lifestyle factors, which in previous LBP literature were deemed important. Unfortunately, the crosssectional nature of the study limited further exploration of causal relationships between the factors investigated. This must be implemented in future studies as there is a scarcity of longitudinal ones within Greece. Also, the lack of exploring similar factors (sociodemographic, physical and lifestyle) in the asymptomatic population approached for recruitment, could have precluded further interpretation of the study's findings.

### 5. Conclusion

LBP point prevalence was found 15% in a general 501 population sample across western and central Greece. 502 Functional limitations, moderately high intensity pain, 503 associated leg pain and recurrence were amongst the 504 highly prevalent physical symptoms in the sample. De-505 spite the sample's mild disability level, perceived phys-506 ical disability and quality of life were correlated with 507 age (as a sociodemographic factor) and two physi-508 cal factors, pain intensity and below knee pain (sci-509 atica). Especially the three-level pain intensity (aver-510 age, 'best' and 'worst' pain intensity) utilised in the 511 study appeared to be one of the most predictive and 512

associative factors for age, as well as several physi-513 cal and lifestyle parameters. Thus, LBP management 514 and clinical research could benefit from the utilisation 515 of a multi-level pain intensity measure. Unlike pre-516 vious literature, most sociodemographic characteris-517 tics (annual income, education, smoking, marital sta-518 tus etc.) were not correlated with any LBP physical 519 or lifestyle factors, thus possibly indicating a differ-520 ent socioeconomic background and aetiology domain 521 to that of the usual non-specific LBP spectrum. Fur-522 ther investigation into this is required. In line with 523 previous reports, significant gender differences were 524 reported across the sample amongst several sociode-525 mographic (education, marital status, smoking, annul 526 income), physical (sciatica and its functionality, pain 527 frequency & intensity, specialist visit, other muscu-528 loskeletal problems) and lifestyle factors (anxiety, de-529 pression and mental wellness). Finally, the fact that 530 physical parameters were amongst the most preva-531 lent characteristics of the Greek sample could provide 532 recommendations on what the 'rehabilitation focus' 533 should entail (i.e. biomedically-functionally orientated 534 rehabilitation rather than psychosocially managed). 535

#### 536 Acknowledgements

The project has been implemented through Oper-537 ational Program "Education and Lifelong Learning" 538 and co-financed by European Union (European Social 539 Fund) and Greek national funds (NSRF 2007–2013). 540 We are thankful to physiotherapists V. Roumelis, 541 M. Hatziantonas, G. Athanasopoulos, P. Gounis, A. 542 Vasilopoulos, P. Grigoriou, A. Kosmas & D. Modiati 543 for their assistance in conducting the survey. 544
