- 23 Preface: The tropics contain the overwhelming majority of Earth's biodiversity: their terrestrial,
- 24 freshwater and marine ecosystems hold over three-quarters of all species, including almost all
- 25 shallow-water corals and >90% of terrestrial birds. Yet, tropical ecosystems are subject to
- 26 pervasive and interacting stressors, such as deforestation, overfishing and climatic change. They
- are also set within a socio-economic context that includes growing pressure from an
- 28 increasingly globalised world, larger and more affluent tropical populations, and the
- 29 continuation of weak governance and limited response capacity. Concerted local, national and
- 30 international actions are urgently required to prevent a collapse of tropical biodiversity.

31 Introduction

- 32 The tropics hold a disproportionate amount of global biological diversity, and are key to meeting
- 33 the international community's aims of socially-just sustainable development and effective
- 34 biodiversity conservation¹. Yet, tropical ecosystems are undergoing rapid environmental, socio-
- 35 economic and demographic change², often driven by forces from extra-tropical, developed
- 36 countries. The scale of these changes is unprecedented, and decisions implemented in the
- 37 coming decades will define the future diversity and sustainability of the tropics.
- 38 Guiding these decisions depends on understanding the diversity and vulnerability of the four
- 39 major tropical ecosystems: the forests and mesic savannas that cover most of the terrestrial
- 40 tropics, the extensive freshwater systems that receive half of the world's rainfall, and the
- 41 shallow-water coral reefs distributed along 150,000 km of coastline (Fig. 1). Here, we quantify
- 42 and review the global importance of tropical biodiversity, evaluate the vulnerability of tropical

1

- 43 ecosystems to proximate stressors, and assess whether global and regional socio-economic
- 44 changes will exacerbate or ameliorate biodiversity loss. We then examine the effectiveness of
- 45 conservation approaches, and highlight the scientific advances required to foster positive
- 46 change and help overcome the challenges arrayed against a sustainable tropical future.

47 The global importance of tropical ecosystems

48 Over evolutionary time, the tropics have acted both as a source and refuge for most extratropical terrestrial and marine species^{3,4}; but just how diverse and irreplaceable are the tropics 49 50 today? The increase in species richness from polar to tropical regions, known as the latitudinal 51 diversity gradient, repeats across a wide range of taxa and biomes. As a result of this gradient, 52 tropical latitudes, which cover just 40% of the Earth's surface, hold a startling proportion of the 53 planet's species: our assessment reveals that almost all shallow-water zooxanthellae corals, 91% 54 of terrestrial birds, and >75% of amphibians, terrestrial mammals, freshwater fish, ants, 55 flowering plants and marine fish have ranges that intersect tropical latitudes (Fig. 2a). For birds, 56 the importance of the tropics extends far beyond 23.5 degrees of latitude, with almost half of all Nearctic species migrating to the Neotropics⁵ and over 2 billion passerine and near-passerines 57 58 crossing the Sahara each autumn⁶. Moreover, a disproportionate number of the world's species 59 are endemic to the tropics. For example, there are 4.5 times more endemic amphibians in the 60 tropics than in temperate regions (Fig 2a). Tropical zones are less important for marine mammals and birds, taxa that peak in diversity at mid-latitudes^{7,8}. Nonetheless, >55% of these 61 62 species use the tropics (Fig. 2a).

- Overall, 78% of species across the ten taxa we assessed occurred within tropical latitudes, but 63 incomplete taxonomic inventories mean that this is almost certainly an underestimate⁹. 64 Between 15,000-19,000 new species are described annually¹⁰, and the majority of recently 65 described terrestrial vertebrates¹¹ or predicted discoveries of invertebrates¹² are from the 66 tropics. Even terrestrial mammals are still being discovered at a rate of c. 25 species a year, with 67 the highest numbers in the Neo- and Afrotropics¹³. Shortfalls in species descriptions for other 68 taxa are often far greater. For example, only 70,000 of an estimated 830,000 multi-cellular 69 plants and animals have been named on coral reefs¹⁴, and the c. 500 spider species described 70 each year represent a tiny fraction of the estimated 150,000 undescribed tropical species¹⁵. 71
- Tropical taxonomic shortfalls are further compounded by a suite of systematic sampling biases. These include undersampling compared with temperate regions¹⁶, the spatial aggregation of sampling effort around coastal areas¹⁷, roads, rivers, urban settlements and high-profile research stations¹⁸, biases in favour of dry-season sampling when many invertebrate taxa are least abundant¹⁹, and the paucity of samples from ecosystems that are harder to access, such as mesophotic and rariphotic reefs²⁰.
- The biological diversity of the tropics is mirrored by many forms of societal diversity²¹. For example, tropical countries contain 40% of the world's population yet 85% of extant languages are spoken within them²². The tropics also provide incalculable benefits to humanity. They house most of the key centres of plant domestication²³ and have been a vital laboratory for the development of science itself – the disciplines of ecology, biogeography and evolutionary

- 83 biology are founded on evidence gleaned from tropical ecosystems. Tropical ecosystems also
- 84 make vital contributions to globally-important ecosystem services: covering just 0.1% of the
- 85 ocean surface, coral reefs provide fish resources for 275 million people that live within 30 km of
- them²⁴ and coastal protection for up to 197 million people²⁵; humid tropical forests cover <12%
- of the world's ice-free land surface but produce 33% of global net primary productivity and
- store 25% of the carbon in the terrestrial biosphere²⁶; while tropical savannas provide a further
- 89 30% of net primary productivity and 15% of carbon storage²⁷. Tropical ecosystems also help
- 90 drive vital atmospheric teleconnections. For instance, 70% of the rainfall in the 3.2M km² *Rio de*
- 91 *la Plata* catchment is estimated to come from evaporation in Amazonia²⁸.

92 Vulnerability of tropical biota and ecosystems

- 93 For all five vertebrate groups with comprehensive IUCN assessments and spatial occurrence data²⁹, globally threatened species are more dependent on the tropics than those classed as 94 Least Concern (Fig. 2b). In addition, 85% of species extinctions from these vertebrate groups 95 have been of species that use the tropics²⁹. Consequently, although extinctions of other groups 96 are less well understood, we can assume that most of the estimated 130,000 modern 97 98 invertebrate extinctions³⁰ will also have been of tropical species. Thus, not only are the tropics 99 vastly more diverse than temperate regions, this diversity is at far greater risk from human impacts³¹. Moreover, given that the tropics have the highest proportion of Data Deficient 100 species and the lowest level of biodiversity-threat assessment¹⁶, information shortfalls mean we 101
- 102 are likely underestimating the vulnerability of the tropical biome. We assessed this vulnerability
- 103 in more depth by examining the effect of local and global stressors, the interactions between
- 104 them, and the resulting changes to tropical ecosystems.

105 Local stressors

- 106 The tropics are subject to some of the highest rates of land-use change and degradation. While 107 the spatial coverage of temperate forests has increased since 1990, tropical deforestation rates 108 exceed 5M ha/yr³². Additional impacts stem from the expansion of large infrastructure projects 109 (e.g. dams) and the growing demand for agricultural commodities, biofuels, timber, fuelwood 110 and other natural resources³³. These all result in severe biotic responses. Even with mitigation, 111 dams present a near-impassable barrier for river fish³⁴, while deforestation replaces a species-
- rich pool of forest-specialists with a smaller pool of common open-area species³⁵. The influence
- of land-use change also extends far into remaining natural areas through isolation and edge
- effects³⁶, additional anthropogenic disturbances³⁷ and altered climatic conditions³⁸. Edge effects
- suppress the abundance of threatened vertebrates up to 200-400 m into tropical forests³⁶,
- 116 leaving almost no core forest refugia in the Brazilian Atlantic Forest where >80% is within 500 m
- of an edge³⁹. Even low levels of landscape modification have significant effects on range-
- restricted species³⁷, and time lags mean that some of the most deleterious effects are observed
 decades after landscape modification⁴⁰.
- 120 Pollution presents a diverse set of threats to tropical ecosystems. Inputs of sediments and
- 121 nutrients from land-use change are well-established drivers of biodiversity loss across
- 122 freshwater⁴¹ and coastal systems, including coral reefs⁴². Pesticide use is increasing across the
- 123 tropics, reflecting rapid intensification of farming practices⁴³ and high pest pressures on tropical

124 crops⁴⁴. Tropical Asian rivers are a major source of the 1.2-2.4 million tonnes of plastic that 125 enters the world's oceans each year⁴⁵, with micro-plastics entering into coral diets⁴⁶ and larger 126 debris increasing rates of coral disease⁴⁷. These examples of chronic pollution are exacerbated 127 by extreme events, such as of the *Fundão* Dam collapse, which released c. 50M m³ of waste into 128 a 600 km stretch of river in south-east Brazil, causing a 7,000 km² toxic plume in the Atlantic

129 Ocean⁴⁸.

130 Overexploitation is also pervasive across the tropics. Fishing has reduced fish biomass by over 75% across a third of coral reefs⁴⁹ and is shrinking the mean body size of exploited freshwater 131 taxa⁵⁰. Hunting contributed to the loss of charismatic mega-herbivores, extirpating African 132 elephants, rhinos and large predators from most of their original ranges^{51,52}. The world's tropical 133 forests are affected by extensive over-harvesting of wildlife³¹, with estimates of the annual 134 harvests of highly-trafficked animals such as pangolins reaching into the millions of individuals⁵³. 135 Moreover, the growth in non-food uses of wildlife means that even small-bodied songbirds are 136 137 at risk of global extinction⁵⁴. Overexploitation also extends beyond fauna and is driving economically valuable tropical trees to extinction⁵⁵. 138

139 Invasive species have been the second most important extinction driver of vertebrates since 1500 CE⁵⁶. Within terrestrial ecosystems, invasive species have exerted the strongest influence 140 on islands and coastal mainlands⁵⁷, having driven thousands of species extinctions and altered 141 trophic structures⁵⁸. On continents, they currently have a greater impact on economically 142 143 developed and extra-tropical regions, but tropical ecosystems are predicted to become 144 increasingly vulnerable to invasion in the 21^{st} century⁵⁹. Despite a deficit of research in the tropics⁶⁰, two prominent examples highlight the scope and magnitude of species invasions into 145 146 terrestrial tropical ecosystems: there has been an 84% increase of alien species detections between 2003 and 2010 in Singapore⁶¹, while invasive African grasses could threaten up to 147 380,000 km² of Australia's savannas by promoting landscape flammability⁶². In aquatic 148 ecosystems, invasive predatory fishes, such as the Indo-Pacific lionfish in Caribbean coral reefs⁶³ 149 and the Nile perch in African lakes⁶⁴, have contributed to the loss of native species. Marine 150 151 invasions are also facilitated by the mass transport of species in ship ballast water, resulting in 152 widespread biotic homogenisation⁶⁵.

153 Global climatic change

154 While many of the "local" stressors described above are promoted by globalised drivers, climate 155 change is truly global. Increases in atmospheric CO₂ concentrations to levels >400 ppm has 156 important implications for tropical terrestrial and aquatic ecosystems. Ocean acidification from 157 dissolved CO₂ is changing ocean chemistry to the extent that declining coral calcification has already been detected⁶⁶. Conditions for reef accretion and growth may be mostly absent 158 159 throughout the tropics by 2100 under business-as-usual emission scenarios⁶⁷. Within savannas, elevated CO₂ levels favour the growth of woody plants over grasses, contributing to woody 160 encroachment and the potential for a switch in biome state 68,69 . CO₂ fertilisation may have also 161 162 contributed to enhanced tree productivity and mortality rates observed in humid tropical 163 forests⁷⁰.

164 Global warming does not proceed at the same rate across the planet. Although the greatest 165 absolute temperature increases are occurring at higher latitudes, the tropics are already some of the hottest places on the planet and have the lowest inter-annual temperature variability 71,72 . 166 Consequently, they will be the first areas to experience significantly warmer climates than the 167 present day⁷² and will endure climatic conditions without present-day equivalents⁷¹. In addition, 168 some of the most important climate oscillations, including El Niño and the Indian Ocean Dipole, 169 170 take place within, and have their greatest influence on, tropical regions. It is unclear if these 171 oscillations will change in a warming world, but extremes of their phases have the potential to 172 exacerbate or ameliorate the overall warming trend. One outcome of increasing temperatures is the poleward shifts of species ranges or movement to higher altitudes or deeper depths⁷³. For 173 example, corals in southern Japan are extending northwards at c. 14 km/yr⁷⁴, and temperate 174 macroalgal communities are being replaced with corals and other tropical species along large 175 stretches of Australian coastline⁷⁵. Latitudinal shifts in terrestrial and freshwater tropical species 176 distributions are less certain because of the many natural and anthropogenic barriers, and the 177 178 low dispersal capacity of many tropical species⁷⁶. Furthermore, the responses of terrestrial species are defined by changes in rainfall as well as temperature⁷⁷. 179

180 If movement is not an option, tropical species must adapt or face extinction. Unfortunately, 181 there is evidence that some species are either approaching their physiological limits or are unable to adapt to the rate of environmental change 78 . Increasing ocean temperature extremes 182 183 are driving mass bleaching events and mortality of reef-forming corals, with the time between 184 bleaching events declining by 76-80% since the early 1980s⁷⁹. Higher temperatures also affect tropical vertebrates, causing, for example, an extreme female bias in the sex ratio of green 185 turtles in the warmer regions of the Great Barrier Reef⁸⁰ and a reduction in the reproductive 186 success of African wild dogs⁸¹. Altered rainfall is also critical. Droughts are drying up biologically 187 diverse small streams⁸², while even modest changes in dry-season length increase tropical tree 188 mortality⁷⁰ and modify tropical forest bird community structure⁸³. 189

- 190 Stressor interactions and indirect effects
- Stressors affecting tropical species can interact in myriad ways⁸⁴. We demonstrate this by
 compiling data from six case studies within a co-tolerance framework that allows species
 responses to two dominant stressors to be examined⁸⁵. Only a small subset of species or genera
 (8-32%) showed no or positive responses when both stressors were combined (Fig. 3), and up to
 55% fell within the "double jeopardy" quadrant, indicating a negative response to both
 stressors. While our summary does not quantify the magnitude of effects, it clearly
 demonstrates that stressors can act together to reduce the abundance or occupancy of tropical
- 198 species. Moreover, these co-tolerance analyses simplify the reality facing tropical ecosystems
- 199 because most are affected by more than two stressors at any given location and time⁸⁴.
- 200 Many changes to tropical ecosystems result from indirect consequences of single or multiple
- 201 stressors. On coral reefs, nutrient inputs from land may increase susceptibility to coral
- 202 bleaching, disease, and outbreaks of pests⁸⁶, while poleward reef expansion is supported by
- 203 feedbacks from range-shifting tropical herbivorous fish⁷⁵. Overexploitation can result in
- 204 surprising changes in tropical ecosystem properties through trophic cascades. For instance, the

- 205 extirpation of a single detritivore fish species in the Orinoco basin reduced downstream organic-
- 206 carbon transport, increasing net primary productivity and respiration⁸⁷. On reefs, overfishing of
- 207 keystone predators has repercussions for benthic structure⁸⁸, while removal of herbivores can
- 208 limit coral recovery from mass-mortality events⁸⁹. In mesic savannas, changes to herbivore
- 209 numbers alter ecosystem functions and structure via their interactions with wildfire regimes⁹⁰.
- 210 Invasive species are also frequently linked to other stressors: the introduction of the Nile perch
- 211 played a major role in the decline of endemic fish species in Lake Victoria, but its effects were
- 212 likely catalyzed by a combination of other drivers including soil erosion, eutrophication and
- 213 overfishing⁶⁴.

214 Ecosystems in transition

215 Interactions between multiple anthropogenic stressors are causing pervasive changes in the

tropics, such that alternate states are emerging across all major tropical ecosystems (Box 1).

217 Perhaps counter-intuitively, trees are encroaching on savannas while grasses are invading

- 218 disturbed tropical forests but in both cases, changes are from species-rich to species-poor
- 219 systems^{68,91}.
- 220 These drastic ecosystem transitions are accompanied by widespread modification of species
- 221 composition. For example, the relative abundance of coral species has been altered on reefs
- that maintain coral dominance⁹²; extirpation of native fish has followed species introductions in
- 223 lakes⁶⁴; liana biomass has increased in otherwise undisturbed Neotropical forests⁹³; and
- 224 patterns of plant regeneration in humid forests have been altered by the overharvesting of
- seed-dispersing vertebrates^{31,94}. Altered species composition is a cause for concern because it
- 226 could signal the onset of more severe modification, especially if dominant species are
- vulnerable or if there are cascading implications for ecosystem functioning. The collapse of
- 228 Jamaican coral reefs provides one of the starkest examples. First, chronic overfishing depleted
- herbivorous fish populations, leaving the system over-reliant on sea urchins for grazing algae.
- 230 Then Hurricane Allen impacted the system in 1980, creating a substantial amount of dead
- substrate. Although corals began recovering after the hurricane, the subsequent mass mortality
- of sea urchins due to disease, combined with the already low abundance of herbivorous fish, led
- to a phase shift from coral to macroalgal dominance 95,96 .

234 Socio-economic context and response capacity

- 235 The interacting proximate stressors causing tropical environmental change are underpinned by
- broader changes in socio-economic and political factors. We examined the trajectories of four
- 237 types of underlying distal drivers, including demography (Fig. 4a-b), socio-political factors (Fig.
- 4c-d), markets (Fig. 4e-f) and technology (Fig. 4g-h)⁹⁷ to explore how tropical countries are
- changing relative to the rest of the world and to evaluate the relative influence of local and
- 240 global drivers. We also examined how the capacity of tropical countries to reduce or cope with
- 241 proximate stressors compares to non-tropical countries based on underlying governance (Fig.
- 242 4i-j) and research capacity (Fig. 4k-l).
- 243 The immense biodiversity of the tropics exists in the context of rapid demographic and
- economic growth (Fig. 4a-b). Human population is growing at a faster rate in the tropics than

elsewhere (Fig. 4a) and by 2050 half of the world's population will live in the tropics². These 245 246 demographic changes are accompanied by steady GDP growth, linked, in part, to the rapid 247 expansion of agricultural and extractive industries. However, tropical per capita GDP – an important measure of human well-being – remains far lower than the non-tropical average (Fig. 248 249 4b), and the rates of change suggest little closing of the inequality gap between global south and north⁹⁸. Although the relationship between development and natural resource conservation 250 does not have to be negative^{99,100}, measures reflecting higher social performance are almost 251 always associated with higher resource use¹⁰⁰. A larger and more affluent tropical population 252 253 will increase demands for timber, water, food, energy, and land, all of which are strongly linked 254 with environmental degradation.

These internal changes will be exacerbated by economic growth in non-tropical countries, and 255 the continued displacement of environmental impacts to less-developed areas¹⁰¹. Indeed, 256 despite high levels of tropical cultural diversity^{21,22}, external socio-political influences (Fig. 4c-d) 257 258 suggest that tropical countries have become increasingly susceptible to globalisation. For 259 example, the proportion of imported food crops (Fig. 4c) and foreign-land acquisitions are far higher in the tropics than elsewhere (Fig. 4d) and are associated with extensive road building¹⁰² 260 and agricultural investment¹⁰³. These trends towards increasing tropical globalisation are 261 262 reinforced by changes in market integration (Fig. 4e-f) and technological development (Fig. 4g-263 h). For example, agricultural exports (Fig. 4e) are steadily increasing, albeit from a far lower 264 baseline than the rest of the world. Moreover, given comparatively low levels of adoption of 265 technological developments, such as industrial fishing techniques (Fig. 4g) or fertilizers (Fig. 4h), there is enormous risk that the rate of natural resource extraction in many tropical countries 266 will increase further, supplying both domestic and export markets^{104,105}. Taken together, these 267 examples highlight the crucial role that external markets will play in determining the fate of 268 269 tropical ecosystems.

Effective environmental governance (Fig. 4i-j) is a necessary condition for improved 270 sustainability outcomes¹⁰⁶, particularly when domestic (Fig. 4a-d) and global (Fig. 4c-f) distal 271 272 drivers are expected to exert increasing and unsustainable pressure on tropical ecosystems^{2,103}. 273 However, the World Bank's national-level assessments of governance effectiveness from the 274 tropics sit in stark contrast to measures from extra-tropical countries, with no sign of 275 improvement (Fig. 4i). External support for environmental governance may help where local 276 governance is weak (Fig. 4). Yet, despite greater OECD (Organisation for Economic Cooperation 277 and Development) environmental aid in the tropics than elsewhere (Fig. 4j), these investments 278 are dwarfed by the value of domestic resource extraction (e.g. agricultural exports; Fig. 4e), the 279 value of which is two orders of magnitude greater than overseas environmental aid. 280 Furthermore, OECD environmental aid has been declining in recent years and seems unlikely to 281 increase in the short term¹⁰⁷.

Low governance capacity in the tropics is further exacerbated by insufficient research and

283 development investment (Fig. 4k) and low levels of scientific output (Fig. 4l). Research

284 investment is critical for driving innovation and the development of evidenced-based solutions

to environmental degradation¹⁰⁸. Despite some notable centres of excellence, the vast majority

of biodiversity-related data and research is concentrated in wealthy, non-tropical countries¹⁷

- and manuscripts submitted by authors from low-income countries are less than half as likely to
- 288 be published as those from high-income countries¹⁰⁹. These trends highlight an alarming
- 289 disconnect between the global scientific process and the people that are most capable of
- 290 engaging with decision makers, who have the best understanding of local context and, arguably,
- 291 have the strongest incentive to achieve positive impacts through their research.

292 Diverse solutions for diverse systems

293 Tropical ecosystems – and therefore at least 78% of the world's biodiversity (Fig. 2a) – are at a critical juncture. Multiple interacting local and global stressors (Fig. 3) that are driving species 294 extinctions and potentially irreversible ecosystem transitions^{92,110} (Box 1) are set within a 295 296 changing socio-economic context (Fig. 4). This changing context is characterised by growing and 297 more affluent populations, an increasingly globalised world, and weak governance and research capacity - all of which threatens to increase environmental degradation, conflict and 298 inequality¹⁰³. Countering these threats requires major improvements in local and global 299 300 governance capacity and a step-change in how environmental objectives are integrated into broader development goals¹¹¹. We review the opportunities and limitations presented by three 301 well-established and non-mutually exclusive approaches to conservation, before highlighting 302 303 priorities for research.

304 *Conservation approaches*

305 A fundamental element of tropical conservation relies on protected areas to limit demographic 306 pressures and the impact of local stressors. These are supported by a wealth of scientific evidence outlining the pervasive impact of local stressors across tropical ecosystems^{37,49} (Fig. 3) combined 307 with an eco-centric philosophy that emphasizes the intrinsic rights of nature¹¹². Yet, despite 308 significant expansion of protected-area coverage in the marine and forested tropics¹¹³, the 309 current network remains poorly designed, has very limited coverage of tropical freshwaters and 310 grasslands, and is inadequately resourced¹¹⁴. Moreover, a strategy focused solely on protected 311 areas will not foster environmental conservation outside of reserves¹¹⁵ and fails to engage with 312 313 the distal drivers of biodiversity loss (Fig. 4) that can undermine the effectiveness of protected 314 areas themselves¹¹⁶.

315 A second set of approaches for tropical conservation is based on the notion that people need to 316 perceive the benefits of nature to justify conservation. These emphasize the need to pursue 317 conservation objectives in human-dominated landscapes, the provision of ecosystem services, and the involvement of private-sector actors. In the tropics, they are epitomised by the growth 318 in market-based conservation payment mechanisms, such as REDD+¹¹⁷, investments in the "blue 319 economy"¹¹⁸ and a step change in the number of companies making sustainability 320 commitments¹¹⁹. These approaches have strengthened the conservation toolkit, especially 321 322 where strict regulatory approaches have failed. Encouraging examples range from the positive effects of commodity certification (e.g. palm oil¹²⁰) to payment for ecosystem service schemes 323 (e.g. watershed protection¹²¹). However, such approaches also attract significant criticism with 324 implementation often lagging commitments¹¹⁹, persistent concerns around the social legitimacy 325 of compensation schemes¹²², and the misalignment of market-based mechanisms with local 326 needs and perceptions of environmental values¹²³. 327

328 A third and more diverse set of approaches is based on recognition of the interdependencies between people and nature, the coevolution of ecological and socio-economic systems at local, 329 regional and global scales¹²⁴, and perspectives about the co-existence of people and nature. This 330 set of more "systems-based" approaches includes: (1) an appreciation of the importance of 331 bottom-up, community-based conservation approaches in human-dominated land- and 332 seascapes (e.g. small-scale fisheries¹²⁵ and community-managed forests¹²⁶); (2) recognition of 333 the role of indigenous people as environmental stewards, and shifts towards an appreciation of 334 more collective relationships with nature (e.g. the Ecuadorian constitution¹²⁷); (3) landscape-335 and ecosystem-wide approaches that attempt to bridge the role of actors working at different 336 scales and in different sectors (e.g. jurisdictional approaches to curb deforestation¹²⁸); and (4) a 337 338 more explicit accounting of multi-scale feedbacks, including the role of distant market actors and distal drivers¹²⁴. These broad, multi-layered "people and nature" approaches hold 339 considerable appeal, but the inherent complexity of local contexts can make them challenging 340 to conceptualize, implement and measure in joined-up and consistent ways¹²⁹. 341

342 Acting together and acting now

343 The three broad approaches to the conservation and governance of tropical ecosystems 344 outlined above are often associated with alternative researcher and practitioner 345 worldviews^{130,131}. But the inherent ecological diversity (Fig. 2a), vulnerability (Figs. 2b & 3) and socio-economic complexity (Fig. 4) of the tropics highlights the importance of pluralism¹³² and 346 the need to adopt a variety of what are often complementary and synergistic approaches¹³¹. For 347 348 all their limitations, protected areas are indispensable to limit the impact of local stressors, and it will be impossible to avoid further biodiversity loss unless they are strengthened and 349 expanded¹³³. However, conservation strategies must also address the underlying drivers of 350 environmental change (Fig. 4) and avoid exacerbating deeply rooted inequalities¹¹⁵. Practice is 351 always messier than theory, and the adoption of more sustainable management systems is 352 353 usually only possible with the support of a range of actors, as can be seen in the recent 354 successes of some hybrid governance approaches, with government, the private sector, and civil society organizations all playing vital roles¹³⁴. 355

- 356 Another clear message is that conservation efforts need to operate at local, regional and global scales to be effective. Many distal drivers are disconnected from sites of impact in both space 357 358 and time, and the engagement of external actors, including in distant markets and governance 359 processes, is often essential to ensure that local efforts are effective. These include more strategic integration of environmental policy with development goals¹³⁵, the need for 360 multinational environmental governance approaches, especially for aquatic systems⁸², and 361 362 recognition of the importance of tackling demand for unsustainable products from downstream buyers and investors¹¹⁹. The capstone of such efforts lies in the urgent need to deliver on the 363 Paris Agreement, without which climate change will undercut or even negate hard-won local 364 conservation successes, whether in coral reefs⁹² or tropical forests¹¹⁰. 365
- Finally, we need to act now to address the pressing environmental challenges facing the tropics.
 This means being adaptive, learning by doing and embracing innovation. The last decades have
 seen a boom in proposals, innovations, and insights about the governance and management of

- tropical ecosystems, ranging from more technocentric proposals to facilitate the evolution of
- 370 climate-tolerant corals¹³⁶; ecological engineering to recover lost trophic interactions by species
- 371 re-introductions, ecological replacements and rewilding¹³⁷; to radical new legal frameworks such
- 372 as France's "Loi de vigilance" (2017-399) that places an unprecedented due diligence obligation
- on major companies to assess social and environmental risks in their supply chains beyond
- 374 French borders. While these innovations serve different purposes and are varyingly scalable,
- they illustrate the potential of solutions-based science and conservation. Of course, acting now
- does not mean ignoring the existing evidence base or making uninformed decisions. Rather, it is
- 377 vital that researchers and decision makers are vigilant to opportunities and risks and are willing
- 378 to learn lessons.

379 Keeping pace with the Anthropocene

All approaches to governing tropical ecosystems will be more effective if they have legitimate local support and are based on strong scientific evidence that ensures, for example, that protected areas are located where they are most needed, ecosystem services are accurately quantified, extractive activities such as fishing and logging are managed sustainably, and underlying drivers of environmental degradation are identified and understood. Whilst these

- challenges are common to all conservation and sustainability science, they are magnified in the
- tropics due to their unique diversity, high vulnerability and the low research capacity of most
- tropical countries. Here, we examine four areas where research effort can be more closely
- aligned with some of the priorities highlighted by this review.

389 Addressing key knowledge shortfalls

390 Our understanding of tropical biodiversity is limited by significant knowledge shortfalls in taxonomy and species distributions¹³⁸. Overcoming these shortfalls will require targeting 391 392 resources towards the information "black holes" that cover large regions of the tropics¹⁸. At the ecosystem level, there is a need for increased study of structurally and functionally distinct 393 systems, particularly tropical grassy biomes⁶⁸, dry forests¹³⁹ and low-order stream systems¹⁴⁰. 394 395 Progress in these areas will likely be aided by significant advances in DNA sequencing and 396 informatics, which have the potential to invigorate taxonomic discovery, and reaching across 397 cultural divides to incorporate national, regional and local knowledge that often remains ignored because it is not in English¹⁴¹, included in standard databases¹⁴², or recognised by 398 conventional science¹⁴³. 399

400 Understanding vulnerability

Our growing knowledge of the role of individual stressors, such as landscape configuration or
 overexploitation, needs to be complemented by research on the impact of multiple stressors⁸⁴,

- 403 which could help predict and mitigate complex biotic responses when climate and local
- 404 stressors act in concert (Fig. 3). Other harder-to-study but important phenomena include the
- 405 role of time lags or extinction debts⁴⁰, trophic cascades³¹, or trajectories of ecosystem
- 406 degradation and recovery in the face of unprecedented environmental change¹⁴⁴. Revealing
- 407 these more complex forms of vulnerability will often demand longer-term and larger multi-scale
- sampling and monitoring programs. New approaches are also needed to overcome one of the

409 more intractable challenges of tropical ecology: we often know least about the rarest and most410 vulnerable species or taxonomic groups.

411 Understanding distal drivers

412 Conservation does not occur in a vacuum, and localised interventions are likely to be much 413 more effective if they are guided by a closer understanding of underlying distal drivers of 414 biodiversity loss and environmental change – including identifying the actors behind such 415 drivers, helping to determine potential trigger points and identifying more effective policy responses⁹⁷. Unpicking the role of distal drivers is essential to understand how distant 416 interactions between social and environmental systems shape local environmental outcomes¹⁴⁵. 417 418 Careful study has revealed many surprising interactions, such as links between the 419 intensification of commercial fishing and increased bushmeat exploitation in west Africa¹⁴⁶, the role of warfare in driving African mammal declines¹⁴⁷, or the role of exchange rates in driving 420 deforestation¹⁴⁸. Achieving this deeper understanding requires greater integration of the natural 421 422 and social sciences, with interdisciplinarity included as a core element of tropical-conservation research¹⁴⁹. 423

424 From research to impact

- 425 Achieving positive impacts from conservation research relies on building a stronger science-
- 426 society interface that challenges the oversimplified assumption of a linear flow from knowledge
- 427 to action¹⁵⁰. Engendering positive changes will require closer participation of practitioners in the
- 428 research process and investments in outreach activities and professional capacity building¹⁵⁰.
- 429 These will be supported by studying the knowledge exchange process itself, including the critical
- 430 role played by knowledge brokers and boundary organizations^{151–153}. Part of this process will
- 431 involve a focus on success stories, or "bright spots", enabling the social, institutional, and
- 432 environmental conditions that create positive outcomes to be identified and replicated¹⁵². The
- 433 positive social and ecological outcomes from innovative restoration and rewilding programmes
- 434 in Costa Rica and Mozambique demonstrate the potential for positive action¹⁵⁴.
- Local managers and scientists have a vital role to play in designing and implementing research
- 436 that can inform regionally-appropriate conservation actions¹⁵⁵ at present, our knowledge of
- 437 hyperdiverse ecosystems is over reliant on inferences gleaned from distant research stations or
- 438 inappropriate temperate theoretical constructs^{18,156}. Research is also more likely to have an
- 439 impact if the spatial scale of studies is more closely matched to the administrative scale at which
- 440 resource decisions are taken¹⁵⁷. Sustaining research programmes and learning networks in study
- 441 landscapes can also help build the vital relationships between researchers, local knowledge
- 442 holders and decision makers¹⁵⁵.
- Achieving these changes requires building on trends in the technological, disciplinary and
- 444 cultural dimensions of research practice. In the technological domain, opportunities for data
- 445 collection have been revolutionised by developments in remote sensing and drones¹⁵⁸, the
- 446 plummeting costs of DNA technologies¹⁵⁹, and the step changes in bioinformatics that have
- allowed big data to be stored and retrieved in open-access platforms¹⁶⁰. In the disciplinary
- 448 domain, the last decade has seen a marked uptick in inter- and transdisciplinary research, with a

- 449 greater though still insufficient integration of natural and social sciences. This has resulted in
- 450 an increasing openness of researchers towards methodological pluralism and mixed-method
- 451 approaches¹⁵⁰ and growing recognition of the contribution that can be made by local people,
- 452 citizen- and para-scientists in biodiversity research¹⁶¹. Changes in research culture include the
- 453 greater internationalisation of ecological science and closer approximation with society¹⁵⁰, both
- of which can help foster a more fertile ground for knowledge exchange and capacity building.
- 455 Notable advances include the development of multi-disciplinary and multinational learning
- 456 networks¹⁶², exponential growth in author teams¹⁶³, and major syntheses such as the
- 457 Intergovernmental Platform for Biodiversity and Ecosystem Services (IPBES).
- 458 Recent years have seen a new awakening of environmental consciousness and calls for decisive
- 459 action, manifest, for example, in the Paris Agreement, the Sustainable Development Goals, and
- 460 voluntary Zero Deforestation Commitments. Tropical and non-tropical scientists can inform
- 461 these endeavours by developing a reliable knowledge base and innovative management
- 462 interventions. Overcoming the remaining research challenges is far from trivial and will require
- 463 a massive investment of resources to develop scientific infrastructure and capacity within
- 464 tropical nations, as well as profound changes to ways of working and the relationship between
- the research process and society at large. But a failure to act decisively and to act now will
- greatly increase the risk of unprecedented and irrevocable biodiversity loss in the hyperdiversetropics.

468 Acknowledgements

489 Figure legends

- 490 **Figure 1 | The tropical biosphere**. **a**, Tropical terrestrial and marine biomes. The tropical
- 491 terrestrial biome (green) was defined as all tropical mesic ecoregions¹⁶⁴. These ecoregions span
- 492 82% of the 50 million km² of land between 23.5° N and 23.5° S, but extend into the subtropics in
- 493 some areas. The tropical marine biome was defined by the 1988-2018 mean minimum monthly
- 494 18 °C sea-surface isotherm. This isotherm bounds the latitudinal extent of shallow-water coral-
- 495 forming ecoregions (blue)¹⁶⁵. **b**, The Intertropical Convergence Zone (ITCZ). The ITCZ was defined
- 496 by 1979-2017 mid-summer (January turquoise colour gradient and July red colour
- 497 gradient) mean monthly total rainfall >20 cm (where both January and July had rainfall >20 cm,
- 498 we show that with the largest total). The ITCZ is a strong predictor of the distribution of tropical
- 499 ecoregions (a). Data sources are presented in Extended Data Table 1.

500 Figure 2 | Tropical hyperdiversity. a, The proportion of species found within tropical latitudes 501 for ten taxonomic groups. Bars are colour-coded to show the percentage of species ranges that 502 overlap the tropics. n gives the total number of species analysed in each group. Black boxes 503 around each bar show the proportion of all species that are endemic to the tropics. Only birds, 504 amphibians and mammals have been comprehensively sampled. Numbers at the end of the bars 505 give the precise percentage of species whose ranges overlap tropical latitudes, as shown in the 506 bars. b, The difference in the proportion of threatened (Critically Endangered, Endangered, and 507 Vulnerable) and non-threatened (Least Concern) species found exclusively within tropical 508 latitudes for the five comprehensively sampled groups. Data from: Birdlife International for birds, the IUCN²⁹ for amphibians and mammals, the Ocean Biogeographic Information System 509 for marine fish, Charlie Veron for shallow-water zooxanthellate corals, Tedesco et al.¹⁶⁶ for 510 511 freshwater fish, and the Global Biodiversity Information Facility for angiosperms. Data sources 512 are presented in Extended Data Table 1.

- 513 Figure 3 | Vulnerability of tropical biota to local and climatic stressors. Species co-tolerance to a local and climate-associated stressor⁸⁵. The x-axis shows responses to fishing for corals (a) and 514 515 reef (b) and freshwater fish (c); land-use change/deforestation for small-stemmed trees ($2 \leq$ 516 DBH <10 cm; (d)) and forest birds (e); and fire suppression for savanna birds (f). The y-axis 517 represents longitudinal responses to climate-associated events: the 2015-16 and 1997-98 coral 518 bleaching events in the Seychelles for, respectively, corals (a) and reef fish (b); the 1997-98 El 519 Niño-induced drought for lower Amazonian freshwater fish (c); Amazonian fires during the 520 2015-16 El Niño for small-stemmed trees (d) and forest birds (e); and shrub encroachment 521 between 1998-2008 in South Africa for savanna birds (f). Species relative density is represented 522 from low (dark blue) to high (light green). The four quadrants represent the location of 523 "Survivor" species tolerant to both stressors (green), species only susceptible to local stressors 524 (yellow), species only vulnerable to climate-associated stressors (blue) and "double-jeopardy" 525 species susceptible to both stressors (red). Numbers show the percentage of species that fall 526 into the quadrant. n gives the total number of species – or genera for corals. Data sources are 527 presented in Extended Data Table 1.
- Figure 4 | Socio-economic drivers of biodiversity loss and societal response capacities. Green
 lines represent countries with >50% of their area within tropical latitudes; purple dashed-lines

531 within tropical countries. a, Global population (1960-2016). b, Gross domestic product (GDP) per capita (2011 \$US based on purchasing power parity; 2000-2016). c, Foreign food crops (1961-532 533 2009). d, Cumulative overseas land ownership (2001-2017). e, Domestic and international 534 airline passengers (1970-2016). f, Agricultural and forestry commodities export value (2001-535 2016). g, Bottom and pelagic trawler catch tonnages (1960-2014). h, Total fertilizer (nitrogen, 536 potash, and phosphate) consumption relative to crop area (2002-2013). i, Government 537 effectiveness index (2000-2016). j, Environmental protection aid (2000-2016). k, Public and 538 private sector research and development expenditure (% GDP) (2000-2015). I, Scientific and 539 technical journal articles per million people in the fields of physics, biology, chemistry, 540 mathematics, clinical medicine, biomedical research, engineering and technology, and Earth and

represent all other countries; grey-shaded areas represent the proportion of the global total

541 space sciences (2003-2016). Data sources are presented in Extended Data Table 1.

543 Box text

- 544 Box 1. Tropical ecosystems in transition.
- Forests (a): Wildfires in historically fire-free humid tropical forests¹⁶⁷ can lead to the dominance 545
- of grassy vegetation that impedes succession towards closed-canopy forests^{91,168}. These 546
- 547 wildfires result from the combination of local actions (e.g. agricultural practices, logging) and
- 548 climate change that has increased wildfire-promoting weather¹⁶⁹.
- Corals (b): Chronic local stressors and acute climatic stressors can lead to coral cover being 549
- replaced by macroalgae, sponges, or sediment-laden turf algae^{89,95}. During the 1998 global 550
- 551 coral-bleaching event, >90% of live coral died in the inner Seychelles and nearly half of the reefs
- 552 transitioned to fleshy macroalgal regimes⁸⁹.
- Savannas (c-d): Woody encroachment is occurring in many savannas⁶⁹, causing biodiversity loss 553
- and altered system functioning⁶⁸. Causes are mixed: regime shifts to forest-associated 554
- 555 ecosystems have been attributed to fire suppression policies (e.g. Brazilian Cerrado [C] to Forest
- $[D]^{170}$), changes in herbivory and increasing atmospheric CO₂⁶⁹. 556

- 557 <u>Freshwater (e):</u> The boom in hydropower-dam construction is affecting large tropical river
- basins¹³⁵. The transformation from lotic to lentic conditions reduces access to riparian and
- floodplain habitats that are nursery areas and feeding grounds for much of the higher biota,
- 560 leading to major shifts in species composition and ecosystem function⁸².

Ecosystems in transition

Wildfires in historically fire-free humid tropical forests¹⁶⁷ can lead to the dominance of grassy vegetation that impedes succession towards closedcanopy forests^{91,168}. These wildfires result from the combination of local actions (e.g. agriculture practices, logging) and climate change that has increased wildfire-promoting weather¹⁶⁹.

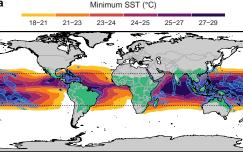

Woody encroachment is occurring in many savannas⁶⁹, causing biodiversity loss and altered system functioning⁶⁸. Causes are mixed: regime shifts to forest-associated ecosystems have been attributed to fire suppression policies (e.g. Brazilian Cerrado [c] to Forest [d] ¹⁶⁹), changes in herbivory and increasing atmospheric CO₂⁶⁹.

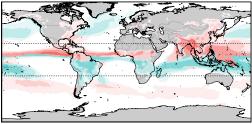

The boom inhydropower-dam construction is affecting large tropical river basins¹³⁵. The transformation of lotic to lentic conditions reduces access to riparian and floodplain habitats that are nursery areas and feeding grounds for much of the higher biota, leading to major shifts in species composition and ecosystem function⁸².
