Abstract

In this paper, we report the synthesis of boron doped C$_3$N$_4$/NiFe$_2$O$_4$ nanocomposite and its application as a visible-light photocatalyst for the degradation of methylene blue (MB). Boron-doped C$_3$N$_4$ (BCN) was prepared by simple thermal condensation of dicyandiamide with boric acid, and NiFe$_2$O$_4$ nanoparticles were prepared by the simple sol-gel method. The as-synthesized nanocomposite materials were characterized and confirmed by the X-ray diffraction spectroscopy, Fourier-transform infrared spectroscopy, field-emission scanning electron microscopy, transmission electron microscopy, UV-Visible diffuse reflectance spectroscopy, X-ray photoelectron spectroscopy, and photoluminescence spectroscopy. The photocatalytic activity of BCN/NiFe$_2$O$_4$ nanocomposite was evaluated towards the degradation of MB in the presence of visible light irradiation. The obtained results confirmed that BCN/NiFe$_2$O$_4$ composite has higher degradation efficiency (98%) than that of BCN and NiFe$_2$O$_4$.

Keywords: Thermal condensation; Sol-gel method; BCN/NiFe$_2$O$_4$ nanocomposite; Visible-light photocatalyst; Methylene blue.
Introduction

The major environmental issues are directly caused by the growth of industrialization with increasing world population leading to depletion of air, soil and water systems [1]. The untreated waste and pollutants discharged from these industries have a high concentration of organic contaminants, salts, dyes, and heavy metals [2]. Among all, dyes and pigments are considered as toxic pollutants due to their harmful effect on to the hydrosphere, agriculture and living organisms [3]. Furthermore, the dye-containing effluents are more stable and non-biodegradable due to its complex structure [4]. To date, different methods have been employed to remove the dyes such as photocatalysis [5, 6], catalytic treatment [7] and chemical treatment [8]. Over the past few decades, the semiconductor photocatalytic technology has emerged as an alternate procedure for the elimination of organic pollutants and to make the pollutant mineralize into CO₂ and H₂O [9].

Carbon nitride (g-C₃N₄) is a well-known semiconductor material, has attracted much attention in a wide range of fields due to its high chemical stability [10], low cost [11], less toxicity [12] and significant bandgap (2.7-2.8 eV) [10]. More recently, g-C₃N₄ incorporated metals [13, 14], metal oxides [13, 15] and non-metals [13, 16] have shown enhanced photocatalytic performance towards the degradation organic dyes than pristine g-C₃N₄. Also, the introduction of non-metals such as boron or sulfur has maintained the metal-free nature of g-C₃N₄ because of their high ionization energy and high electronegativity [17]. Among different non-metals, boron is a lightweight element and forms a stable chemical bond with the g-C₃N₄ [18]. Due to the discussed unique properties, it can often alter the photocatalytic activity of g-C₃N₄ when combined with other semiconductor materials [19]. The useful addition of semiconductor materials into the boron doped g-C₃N₄ (BCN) matrix can reduce the energy band gap and electronic structure which may eventually increase the electron-hole separation and the catalytic activity [20]. More recently, the spinel ferrite structures (MFe₂O₄, M=Zn, Ni, Co) have found significant interest in the application of organic dye degradation [5, 21] and water splitting reactions [22, 23]. In particular, nickel ferrite (NiFe₂O₄) is a well-known visible-light semiconductor and having a
narrow band gap of 2.19 eV with decent photocatalytic stability [24]. Recent studies revealed that the photocatalytic activity of C$_3$N$_4$ had been improved in the visible light region when combined with noble metal and metal oxides [25]. The heterojunction structure of the semiconductor composites is the main reason for the enhanced photocatalytic activity. However, NiFe$_2$O$_4$ decorated BCN nanocomposite has never been used for the photocatalytic applications. Given the above points, the integration of unique properties of BCN with NiFe$_2$O$_4$ could enhance the photocatalytic activity of organic dyes than that of the pure BCN and NiFe$_2$O$_4$.

In this present work, we report the synthesis of BCN/NiFe$_2$O$_4$ nanocomposite for the first time. The as-prepared BCN/NiFe$_2$O$_4$ nanocomposite was used as a novel visible-light catalyst for the photodegradation of organic dye, and methylene blue (MB) was used as a model dye for the photocatalytic measurements. The photocatalytic activity of BCN, NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ towards the degradation of MB was studied and discussed in detail. The photocatalytic degradation mechanism of MB using the photocatalyst has also been discussed.

Experimental

Materials

Iron chloride (FeCl$_3$, 98%, Alfa Aesar, WH, USA), nickel chloride (NiCl$_2.6$H$_2$O, Sigma Aldrich, MO, USA), boric acid (H$_3$BO$_3$, J.T. Baker, CV, PA), dicyandiamide (C$_2$H$_4$N$_4$, 99%, Alfa Aesar, UK), sodium hydroxide (NaOH, Nihon Shiyaku Industries Ltd., Taiwan) and double distilled water was used throughout the experiment. All chemicals used in this work were of analytical grade and were used as received.

Synthesis of BCN

BCN was prepared by thermal polycondensation reaction using dicyandiamide and boric acid [25]. Briefly, 1.68 g of dicyandiamide and 0.6 g of boric acid were evenly grounded using an agate mortar. Further, this mixture was placed into a crucible with a lid and heated in a muffle furnace at 550
°C for 3h with a heating rate of 5°C min⁻¹. The final powder was collected, washed with ethanol followed by water and dried in an oven for 5 hr at 80°C.

**Preparation of BCN/NiFe₂O₄ nanocomposite**

The following procedure was used for the preparation of BCN/NiFe₂O₄ nanocomposite. First, the dispersion of BCN (1 g) in 100 mL water was prepared using ultra-sonication method (30 min). About 1 M of NiCl₂ and 2 M of FeCl₃·9H₂O was added into the above dispersion with continuous stirring. The pH of the solution was maintained at pH~13 using 3 M NaOH. Then, the emulsion was stirred for 1 h at 80°C using magnetic stirrer and dried at 90°C. The obtained powder was calcined for 3h at 450°C with a heating rate of 5°C min⁻¹. The obtained sample was labeled as BCN/NiFe₂O₄ nanocomposite. The similar procedure was used for the preparation of the NiFe₂O₄ and was prepared without BCN.

**Characterization**

The structural patterns and crystallite size of the synthesized materials were analyzed by the X-ray diffractometer (XRD) PANanalytical X’Pert PRO instrument with CuKα radiation (λ=1.5418 Å). The surface morphology and elemental analysis of as-synthesized nanocomposite materials were analyzed using a JEOL-JEM2100F transmission electron microscopy (TEM) and JEOL JSM-7100F field-emission scanning electron microscope (FESEM). Fourier-transform infrared (FT-IR) spectra were obtained by Perkin Elmer FT-IR spectrometer. The FT-IR sample pellets were prepared using KBr substrate with synthesized different materials. UV–visible diffuse reflectance spectra (UV-DRS) was analyzed using Cary 5000 UV-Vis-NIR spectrophotometer with an integrating sphere attachment. A spectralon blank was used as the reference. The X-ray photoelectron spectroscopy (XPS) was analyzed by JEOL JPS-9030. Photoluminescence (PL) spectroscopy was measured using Dongwoo-Ramboss 500i, Gyeonggi-Do, Korea.

**Photodegradation Experiments**

For the degradation experiments, the MB was used as a model textile pollutant to evaluate the catalytic performance of as-synthesized materials. The Mercury-Xenon lamp (350 W, 0.33 mW cm⁻²,
Prosper Technology, Taiwan) light was used as a visible light source. For the experiment, 100 mL of MB (5 ppm) dye was mixed with 100 mg of BCN/NiFe$_2$O$_4$ nanocomposite. Before the light introduction, the above mixture was stirred for 30 minutes to obtain dye-catalyst adsorption equilibrium. At a preset time (5 min), about 4 mL of the dispersion was drawn and filtered for the UV measurements.

Results and discussion

Characterization of the as-synthesized materials

The structural and phase information of all the samples were characterized by XRD. Fig. 1A shows the two distinct diffraction peaks for typical BCN at 26.9° and 43.8° which can be indexed as (002) and (100) planes (JCPDS card No. 34-0421) [26]. The significant broad peak at (002) attributes to the higher inter-planar distance like boron nitride and graphite. The plane (100) is due to the in-plane reflections of BCN [27, 28]. The diffraction peak pattern of NiFe$_2$O$_4$ detected at 30.15°, 35.65°, 44.49°, 51.95°, 57.24° and 62.96° which are designated by their corresponding indexes 220, 311, 400, 422, 511 and 440 respectively (JCPDS 74-2081) [24]. The peaks at 26.74°, 35.65°, 44.49°, 51.95°, 57.24°, 62.96° can be ascribed to the (002, 220, 311, 400, 422, 511 and 440) of BCN/NiFe$_2$O$_4$ nanocomposite. The results confirmed the successful formation of BCN/NiFe$_2$O$_4$ nanocomposite.

![Fig. 1 A) XRD patterns of as-synthesized BCN, NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ nanocomposite. B) FT-IR spectra of BCN, NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ nanocomposite.](image)
The FT-IR spectra of BCN, NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ nanocomposites are shown in Fig. 1B. The NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ nanocomposite shows a broad vibration band at 3100-3500 cm$^{-1}$ and is due to the stretching vibrations of N-H or O-H group. The peaks in BCN from 1200 to 1700 cm$^{-1}$ can be attributed from the vibrational stretching band of C-N and C=N, and the peak around 806 cm$^{-1}$ shows the band of triazine units \[29\]. The peaks of in-plane B–N and B–C are observed at 1462 and 1273 cm$^{-1}$ respectively \[30, 31\]. In NiFe$_2$O$_4$, the stretching vibrations of Fe–O bonds in tetrahedral positions and metal–O bonds in octahedral positions shows the sharp peak at 592 cm$^{-1}$ and a weak peak at 466 cm$^{-1}$ respectively \[32\]. For BCN/NiFe$_2$O$_4$ nanocomposite, the bands at 1652, 1450 and 579 cm$^{-1}$ assigned to BCN, B-N vibration and Fe-O bonds respectively. The result confirmed that the structure of BCN and NiFe$_2$O$_4$ remains unchanged in the nanocomposite.

The surface morphology of the synthesized materials was analyzed by the FESEM, and the corresponding FESEM images are shown in Fig. 2. In Fig. 2A, a rough sheet-like structure was observed for BCN. Fig. 2B shows the aggregated particles of NiFe$_2$O$_4$ with the average diameter around 100 nm. This variable size of the particles is due to the synthesis process including milling in an agate mortar \[33\]. The Fig. 2C represents the BCN/NiFe$_2$O$_4$ nanocomposite with aggregated NiFe$_2$O$_4$ nanoparticles embedded on the sheet-like BCN. The size of the NiFe$_2$O$_4$ nanoparticles was reduced after incorporated with BCN than primary NiFe$_2$O$_4$ particles. The reduced size of the nanoparticles is may be due to the presence of more surface area and photogenerated electrons and holes of BCN. The elemental analysis (Fig. 2D) and elemental mapping (Fig. 2 E-J) results of the BCN/NiFe$_2$O$_4$ nanocomposite confirmed the presence of C, O, B, Ni, N, and Fe.
Fig. 2 FESEM images of BCN (A), NiFe$_2$O$_4$ (B), BCN/NiFe$_2$O$_4$ nanocomposite (C) and elemental analysis (D) and elemental mapping of O, Fe, Ni, C, N, and B (E-J) on BCN/NiFe$_2$O$_4$ nanocomposite.
TEM was also performed to examine the structural morphology of as-prepared BCN, NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ nanocomposite. **Fig. 3** shows the TEM images of BCN (A), NiFe$_2$O$_4$ (B) and BCN/NiFe$_2$O$_4$ nanocomposite (C). **Fig. 3A** shows the sheet-like structure of BCN and the agglomerated NiFe$_2$O$_4$ nanoparticles are visible in **Fig. 3B. Fig. 3C** confirmed that NiFe$_2$O$_4$ nanoparticles embedded on the surface of BCN. The obtained TEM images of BCN, NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ nanocomposite has found to similar to the morphology of FESEM.

![Fig. 3 TEM images of BCN (A), NiFe$_2$O$_4$ (B) and BCN/NiFe$_2$O$_4$ nanocomposite (C).](image)

The UV-DRS of the as-prepared composite material were measured in the wavelength ranges between 200 and 800 nm. **Fig. 4A** shows the UV-DRS of BCN, NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ nanocomposite. The BCN and NiFe$_2$O$_4$ show the band edge wavelengths in the visible light region of 200-800 nm. It can be seen that the band edge of the BCN/NiFe$_2$O$_4$ nanocomposite increases compared with BCN and NiFe$_2$O$_4$ which indicates the effective absorption of visible light by the BCN/NiFe$_2$O$_4$ nanocomposite than others. **Fig. 4B** shows the indirect bandgap of BCN/NiFe$_2$O$_4$ nanocomposite about 2.05 eV, and it was lower than that of BCN (2.65 eV) and NiFe$_2$O$_4$ (2.38 eV).
Fig. 4 UV-DRS of BCN, NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ nanocomposite (A), the indirect band gap of as-prepared BCN, NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ nanocomposite (B).

The surface elemental composition and the electronic state of the BCN/NiFe$_2$O$_4$ nanocomposite were characterized by XPS analysis and is shown in Fig. 5. The binding energies of B 1s, C 1s, N 1s, Ni 2p, Fe 2p and O 1s of the nanocomposite are shown in Fig. 5 (A-F). The characteristic peak at 191.2 eV reveals the binding energy of B 1s and confirms the presence of B-N [34]. A broad peak of C1s includes C=C, C−O, C−N and C−B components appeared at binding energies of 284.9 eV, 288.4 eV, 285.6 eV, and 283.8 eV respectively [35]. The N 1s spectrum also includes the binding energies to pyridinic nitrogen at 398.6 eV, C-N-H group at 399.5 eV and graphitic nitrogen at 400.7 eV [36]. The binding energy of Ni 2p$_{3/2}$ appears at 856.9 eV, and Ni 2p$_{1/2}$ appears at 875.1 eV [37]. For the binding energy of Fe 2p appeared at 711.1 eV and attributed to Fe 2p$_{3/2}$. The peak at 724.4 eV indicates the presence of Fe 2p$_{1/2}$ [38]. The characteristic peak at 532.5 eV shows the O 1s in the NiFe$_2$O$_4$ composite at which is assigned for the O$^2$ and spinel metal oxides [38].
Fig. 5 High-resolution XPS spectra (B 1s, C 1s, N 1s, Ni 2p, Fe 2p, and O 1s) of as-synthesized BCN/NiFe$_2$O$_4$ nanocomposite.

Photoluminescence spectroscopy

The PL spectra of BCN/NiFe$_2$O$_4$, NiFe$_2$O$_4$, and BCN, are shown in Fig. 6. A broad peak at 415 nm is observed for the BCN which exhibits the higher recombination rate of electron-hole pairs. Fig. 6 inset shows the reduced PL intensities of NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ which infers a significant reduction in the recombination rate when compared to BCN. There is a decrease in the emission peak intensity of BCN/NiFe$_2$O$_4$ which also indicates the effective $e^-/h^+$ charge separation and increases the transfer efficiency from the valence band to the conduction band. Further, NiFe$_2$O$_4$ nanoparticles incorporated with BCN behaves as an electron acceptor and thus increases the photocatalytic activity.
Fig. 6 PL spectra of BCN and NiFe$_2$O$_4$, BCN/NiFe$_2$O$_4$ nanocomposite (inset)

**Photo-catalytic degradation of MB**

Fig. 7A shows the photo-catalytic degradation of MB by the as-prepared nanocomposite in the presence of visible light irradiation at a different time. It can be seen that the decrease in intensity at 664 nm with the increasing the visible light irradiation time. The result indicates the effective photodegradation of MB by the BCN/NiFe$_2$O$_4$ nanocomposite. A plot of time vs. the percentage of dye remaining in the solution is shown in Fig. 7B. The obtained results revealed that the degradation efficiencies of 25.6, 69 and 98% were obtained using NiFe$_2$O$_4$, BCN and BCN/NiFe$_2$O$_4$ nanocomposites at 80 min.
Fig. 7 Photocatalytic degradation of MB in the presence of BCN/NiFe$_2$O$_4$ nanocomposite (A). A plot of time vs. % of dye remaining in the solution (B).

Photodegradation mechanism of MB

The synergistic effect between BCN and NiFe$_2$O$_4$ results in the enhanced photocatalytic activity and higher adsorption of MB on the catalyst surface. As discussed earlier that the as-synthesized nanocomposite has lower bandgap (2.05 eV) than that of BCN (2.65 eV) and NiFe$_2$O$_4$ (2.38 eV). The lower bandgap of the BCN/NiFe$_2$O$_4$ nanocomposite will help to achieve the enhanced photocatalytic activity towards the degradation of MB. Also, the recombination rate of BCN was reduced upon composite with NiFe$_2$O$_4$, and resulting in the higher electron-hole separation and a considerable population of e$^-$/h$^+$ pairs. The migration of electrons from the CB of BCN to the CB of NiFe$_2$O$_4$ causes a high negative (e$^-$) rich environment which also makes slightly positive VB of NiFe$_2$O$_4$. The holes on the VB of NiFe$_2$O$_4$ migrate to VB of BCN simultaneously. This process of redistribution of electrons-holes delays the recombination rate of the photoinduced carriers. The increased recombination rate of electrons and holes could reduce the catalytic activity due to the lack of producing OH$^-$ and O$_2$•$^-$. When the reaction medium introduced into the visible light irradiation, the valence band (VB) electrons were excited to the conduction band (CB), this photogenerated e$^-$ and h$^+$ involved in the production of OH$^-$ and O$_2$•$^-$. The as-formed OH$^-$ and O$_2$•$^-$ radicals can oxidize the MB into the degradation
products such as CO$_2$ and H$_2$O. The mechanism of the photodegradation of dye can be expressed by the following equations (Eqn. 1–4).

\[
\text{BCN/Fe}_2\text{O}_4 + \text{hv} \rightarrow \text{VB} (h^+) + \text{CB} (e^-) \tag{1}
\]

\[
\text{VB} (h^+) + \text{H}_2\text{O} \rightarrow \text{OH}^+ + \text{H}^+ \tag{2}
\]

\[
\text{CB} (e^-) + \text{O}_2 \rightarrow \text{O}_2^- \tag{3}
\]

\[
\text{OH}^+ + \text{O}_2^- + \text{dye} \rightarrow \text{degradation products} \tag{4}
\]

The kinetics and rate constant of the photocatalytic degradation reaction using NiFe$_2$O$_4$, BCN and BCN/NiFe$_2$O$_4$ are shown in Fig. 8A. A plot of ln(C/Co) vs. time follows the pseudo-first order kinetics. The rate constant (k') value of BCN/NiFe$_2$O$_4$ nanocomposite (k'=4.4 x 10$^{-2}$ min$^{-1}$) was obtained from the intercept of the linear line which was 12.7 times greater than NiFe$_2$O$_4$ (k'=3.5 x 10$^{-3}$ min$^{-1}$) and 3.2 times greater than that of BCN (k'=1.4 x 10$^{-2}$ min$^{-1}$). The correlation coefficient ($R^2$) values of BCN, NiFe$_2$O$_4$ and BCN/NiFe$_2$O$_4$ nanocomposite materials are found to be 0.9608, 0.9595 and 0.9796 respectively.

**Fig. 8 A**) Pseudo-first order kinetics of photodegradation using NiFe$_2$O$_4$ (a), BCN (b), BCN/NiFe$_2$O$_4$ (c), and reusability of BCN/NiFe$_2$O$_4$ nanocomposite (B).

**Reusability**

The economic feasibility and practical usability of a photocatalyst material are analyzed with the reusability studies. Hence, the reusability studies of the BCN/NiFe$_2$O$_4$ nanocomposite are shown in Fig.
After the degradation, the catalyst nanocomposite was collected by centrifugation. Then, it was washed with deionized water and ethanol to remove the adsorbed MB molecules and dried in an oven for 3 h. The collected nanocomposite was used subsequently to measure the photocatalytic efficiency. From the obtained results, the percentage degradation of MB was calculated to be 97.68%, 96.23% and 95.99% for three successive cycles. The result indicates the excellent cyclic stability of the BCN/NiFe$_2$O$_4$ nanocomposite.

**Fig. 9** Degradation % of MB using BCN/NiFe$_2$O$_4$ nanocomposite in the presence of different scavenging species (scavengers).

To understand the role of the active species generated during the photocatalytic reaction, ethylenediaminetetraacetic acid (EDTA), K$_2$S$_2$O$_8$ (PP), acrylamide (AA) and tertiary butyl alcohol (T-BuOH) were used as the scavenger materials to trap holes (h$^+$), electrons (e$^-$), superoxide radicals (•O$^{2-}$) and hydroxyl radicals (•OH) respectively. The degradation process without scavengers shows 98% of MB degradation after 80 min. After the addition of EDTA, PP, AA, and T-BuOH scavengers into the system, the degradation percentage of MB was 81.2, 96.87, 44.0 and 85.1% respectively (Fig. 9). The
results indicate that the contribution of active species in the photodegradation of MB as in the order of 
\( \cdot \text{O}_2^- > \cdot \text{OH} > h^+ > e^- \). Therefore, the degradation of MB significantly reduced because of the addition of AA 
to capture the \( \cdot \text{O}_2^- \). On the other hand, the degradation percentage of MB slightly decreased when PP,
T-BuOH, and EDTA were added to the system.

**Conclusion**

In conclusion, a novel BCN/NiFe\(_2\)O\(_4\) photocatalyst was prepared by simple thermal 
condensation and sol-gel methods for the first time. The synthesized materials were confirmed by 
different physicochemical techniques. The as-synthesized nanocomposite material was used for the 
effective degradation of MB. The obtained results revealed that BCN/NiFe\(_2\)O\(_4\) nanocomposite had 
better catalytic activity towards MB than that of pristine NiFe\(_2\)O\(_4\) and BCN. The degradation of the MB 
was confirmed by intensity variations of its UV absorption peaks, and the obtained results confirmed the 
pseudo-first-order kinetics mechanism. As a future perspective, the synthesized BCN/NiFe\(_2\)O\(_4\) 
nanocomposite can be used as a low-cost photocatalyst material for the applications of environmental 
decontamination of organic dyes.

**Highlights**

- For the first time, BCN/NiFe$_2$O$_4$ nanocomposite has been used for the photocatalytic degradation of organic dye.
- MB has been used as a model organic dye to study the photocatalytic behavior of synthesized nanomaterials.
- The photocatalyst can able to degrade 98% of MB within 80 min under visible light irradiation.
- The BCN/NiFe$_2$O$_4$ nanocomposite has enhanced photocatalytic activity towards MB than that of BCN and NiFe$_2$O$_4$.
- The as-synthesized nanocomposite photocatalyst had excellent cyclic stability.
