## 51 Abstract

52

53 **Purpose:** The purpose of this study was to investigate the within-session reliability of  
54 bilateral and unilateral stance isometric mid-thigh pull (IMTP) force-time characteristics  
55 including peak force (PF), relative PF and impulse at time bands (0-100, 0-200, 0-250 and 0-  
56 300 ms); and to compare isometric force-time characteristics between right and left and  
57 dominant (D) and non-dominant (ND) limbs. **Methods:** Professional male Rugby league and  
58 multi-sport collegiate male athletes ( $n=54$ , age  $23.4 \pm 4.2$  years, height  $1.80 \pm 0.05$  m, mass:  
59  $88.9 \pm 12.9$  kg) performed 3 bilateral IMTP trials, and 3 unilateral stance IMTP trials per leg  
60 on a force plate sampling at 600 Hz. **Results:** Intraclass correlation coefficients (ICC) and  
61 coefficients of variation (CV) demonstrated high-within session reliability for bilateral and  
62 unilateral IMTP PF (ICC =.94, CV = 4.7–5.5%). Lower reliability measures and greater  
63 variability were observed for bilateral and unilateral IMTP impulse at time bands (ICC =.81-  
64 .88, CV =7.7-11.8%). Paired sample t-tests and Cohen's  $d$  effect sizes revealed no significant  
65 differences for all isometric force-time characteristics between right and left limbs in  
66 collegiate male athletes ( $p >.05$ ,  $d \leq 0.32$ ) and professional rugby league players ( $p >.05$ ,  $d$   
67  $\leq 0.11$ ), however significant differences were found between D and ND limbs in male  
68 collegiate athletes ( $p <.001$ ,  $d = 0.43-0.91$ ) and professional rugby league players ( $p <.001$ ,  $d$   
69  $= 0.27-0.46$ ). **Conclusion:** This study demonstrated high within-session reliability for  
70 unilateral stance IMTP PF; revealing significant differences in isometric force-time  
71 characteristics between D and ND limbs in male athletes.

74

## 75 Introduction

76

77 Muscle strength asymmetry (MSA) refers to the relative strength differences and deficits  
78 between limbs,<sup>1</sup> with a strength discrepancy of 10-15% or more between two sides  
79 considered to represent a potentially problematic asymmetry.<sup>2</sup> Higher MSA indexes have  
80 been suggested to place athletes at a greater risk of injury,<sup>3 4,5</sup> conversely researchers have  
81 demonstrated no connection between MSA and injury.<sup>6,7</sup> However, there is no specific value  
82 in the literature that represents the threshold between injured and non-injured athletes, or  
83 values that definitively identify an increased injury risk in athletes.<sup>8</sup> It should be noted that  
84 asymmetries may be a positive adaptation of the sport, developed by specific sporting  
85 demands.<sup>9</sup> In terms of athletic performance previous studies have also shown MSA can  
86 negatively impact performance during change of direction,<sup>10</sup> vertical jumping,<sup>11, 12</sup> and  
87 kicking.<sup>13</sup> However, asymmetry index values for athletic performance measures have yet to  
88 be established.<sup>14</sup>

89

90 Muscle strength asymmetry has typically been assessed in athletes via isokinetic  
91 dynamometry,<sup>3,14</sup> vertical jump,<sup>12</sup> and multidirectional jump and hop tasks;<sup>15</sup> with research  
92 suggesting that the magnitude of MSA are task dependant.<sup>14, 15</sup> More recently researchers  
93 have investigated isometric bilateral asymmetries through isometric squat<sup>13, 16</sup> and isometric  
94 mid-thigh pull (IMTP)<sup>11, 17-19</sup> assessments via a dual force plate system. Interestingly,  
95 isometric asymmetrical differences have been observed between dominant (D) and non-  
96 dominant (ND) limbs for peak force,<sup>11, 17-19</sup> and time-specific force values,<sup>18, 19</sup> with  
97 researchers reporting larger asymmetries in weaker athletes<sup>16-18</sup> and female athletes<sup>18, 19</sup> in  
98 comparison to stronger athletes. Moreover, larger asymmetries have been associated with  
99 lower jump heights and lower peak power in loaded and unloaded jumps.<sup>11</sup> However, block  
100 periodised strength training has been shown to reduce bilateral asymmetries in weaker

101 athletes.<sup>16</sup> Therefore, the assessment of lower limb MSA allows scientists and practitioners to  
102 monitor and identify higher imbalanced athletes to subsequently design effective training  
103 programs to reduce strength imbalances. This could potentially reduce risk of injury and  
104 improve athletic performance.

105  
106 Jumping, sprinting and change of direction (COD) movements are unilateral, requiring  
107 unilateral propulsive force production. Researchers have investigated unilateral force  
108 production through unilateral jump assessments in relation to athletic performance tasks<sup>10, 20</sup>  
109 and to investigate imbalances between lower limbs.<sup>15, 21</sup> To our knowledge, previous  
110 investigations have only assessed unilateral isometric force-time characteristics via an  
111 unilateral isometric squat<sup>13, 22, 23</sup> demonstrating high reliability measures. However, as IMTP  
112 assessments are becoming more common in testing batteries in various athletic populations,<sup>18,</sup>  
113 <sup>24</sup> and yield high reliability and low measurement error in force-time variables;<sup>24, 25</sup> it is  
114 somewhat surprising that a unilateral stance IMTP has yet to be investigated for assessing  
115 MSA.

116  
117 As previously stated bilateral asymmetries have been established during bilateral IMTP  
118 assessments via a dual force plate system,<sup>11, 18, 19</sup> however a unilateral stance IMTP would  
119 allow direct comparisons between left and right limbs to establish any MSA indexes and the  
120 identification of D and ND limbs. Furthermore, given the unilateral force production  
121 requirements of sprinting, jumping and COD movements, arguably a unilateral stance IMTP  
122 would be more specific to these dynamic sporting movements. Although the relationship of  
123 MSA and injury risk remains inconclusive, from a performance perspective it would be  
124 advantageous being equally proficient at producing force in both lower limbs,<sup>14</sup> given the  
125 unpredictable nature of multidirectional sports where athletes must change direction, jump  
126 and land off either limb in response to stimuli.

127  
128 The aims of this study were firstly to assess the within-session reliability of bilateral and  
129 unilateral IMTP force-time characteristics (Peak force [PF], relative PF, impulse at time  
130 bands 0-100, 0-200, 0-250, 0-300 ms). Secondly, to compare left and right and D and ND  
131 limbs to determine if any significant differences and imbalances were present between limbs.  
132 Thirdly, to establish normative MSA ranges for male collegiate athletes and professional  
133 male rugby league players. It was hypothesized that the unilateral IMTP would demonstrate  
134 high reliability, similar to the bilateral IMTP. Further, it was hypothesized that no significant  
135 differences will be found in isometric force-time characteristic between left and right limbs,  
136 but that significant differences would be observed between D and ND limbs.

137

## 138 **Methods**

139

### 140 **Subjects**

141 54 male athletes consisting of 35 professional male rugby league players (age  $24.2 \pm 4.8$   
142 years, height  $1.81 \pm 0.06$  m, mass  $94.5 \pm 11.2$  kg) and 19 collegiate male athletes (soccer  $n=7$ ,  
143 rugby  $n=2$ , boxing  $n=2$ , weightlifting  $n=2$ , water polo  $n=1$ , cricket  $n=1$ , judo  $n=2$ , American  
144 football  $n=2$ ) (age  $21.7 \pm 2.3$  years, height  $1.80 \pm 0.05$  m, mass  $78.4 \pm 7.9$  kg) provided  
145 informed consent to participate in this study which was approved by the institutional review  
146 board. All subjects were familiar with the IMTP and possessed  $>2$  years resistance training  
147 experience. At the time of testing, the rugby athletes were at the end of pre-season and  
148 collegiate athletes were currently in season.

149

### 150 **Design**

151 A within subjects design was used to determine any significant differences in isometric force-  
152 time characteristics (PF, relative PF, impulse at time bands 0-100, 0-200, 0-250, 0-300 ms)  
153 between left and right and D and ND limbs during the unilateral IMTP; and to determine  
154 MSA indexes between limbs. Subjects performed three maximal bilateral IMTPs, and 3  
155 unilateral stance IMTP trials per leg on a force plate sampling at 600 Hz. Within-session  
156 reliability was assessed for all isometric force-time characteristics for both bilateral and  
157 unilateral IMTPs.

158

## 159 **Procedures**

160

### 161 **Pre-isometric warm up**

162 All subjects performed a standardized warm-up outlined in previous research,<sup>26</sup> comprising of  
163 5 minutes of dynamic stretching before advancing to dynamic mid-thigh clean pulls. One set  
164 of 5 repetitions was performed with an empty barbell (Werksan Olympic Bar, Werksan,  
165 Moorsetown, NJ, USA) followed by 3 bilateral isometric efforts at perceived intensities of  
166 50%, 70%, and 90% of maximum effort, interspersed with 1-minute recoveries.

167

### 168 **Bilateral and unilateral isometric mid-thigh pull protocol**

169 Bilateral IMTP testing followed similar protocols used in previous research.<sup>27</sup> The IMTP  
170 testing was performed on a portable force plate sampling at 600 Hz (400 Series Performance  
171 Force Plate, Fitness Technology, Adelaide, Australia) using a portable IMTP rack (Fitness  
172 Technology, Adelaide, Australia). Sampling as low as 500 Hz has been shown to produce  
173 high reliability measures for isometric force-time variables.<sup>26</sup> The force plate was interfaced  
174 with computer software [Ballistic Measurement System (BMS)] which allowed direct  
175 measurement of force-time characteristics.

176 For the bilateral stance IMTP testing, a collarless steel bar was positioned to correspond to  
177 the athlete's second-pull power clean position<sup>24</sup> just below the crease of the hip. The bar  
178 height could be adjusted (3 cm increments) at various heights above the force plate to  
179 accommodate different sized athletes. Athletes were strapped to the bar in accordance to  
180 previous research<sup>28</sup> and positioned in their self-selected mid-thigh clean position established  
181 in the familiarization trials whereby feet were shoulder width apart, knees were flexed over  
182 the toes, shoulders were just behind the bar, and torso was upright.<sup>26</sup> Researchers have  
183 demonstrated that differences in knee and hip joint angles during the IMTP do not influence  
184 kinetic variables<sup>25</sup> justifying the self-selected preferred mid-thigh position. All subjects  
185 received standardized instructions to pull as fast and as hard as possible and push their feet  
186 into the force plate until being told to stop, as these instructions have been shown to be  
187 optimal in producing maximum PF and RFD results.<sup>28</sup> Once the body was stabilised (verified  
188 by watching the subject and force trace) the IMTP was initiated with the countdown "3, 2, 1  
189 pull," with subjects ensuring that maximal effort was applied for 5 seconds based on previous  
190 protocols;<sup>24, 28</sup> data was collected for a duration of 8 seconds. Minimal pre-tension was  
191 allowed to ensure there is no slack in the body prior to initiation of pull. Verbal  
192 encouragement was given for all trials and subjects. Subjects performed a total of 3 bilateral  
193 maximal effort trials and interspersed with 2-minute recoveries.

194

195 Unilateral stance IMTP testing followed the same procedures outlined for bilateral IMTP  
196 testing however was only performed with one foot on the force platform with the other limb  
197 flexed 90° at the knee. Subjects were positioned at the same hip and knee joint angle  
198 established during bilateral testing. Subjects were instructed to maintain balance and pull as  
199 fast and as hard as possible and pushing their single foot into the force plate. Subjects

200 performed a total of six unilateral maximum effort trials (3 with left and right limbs each) in  
201 an alternating order, interspersed with 2-minute recoveries. Any trials whereby subjects lost  
202 balance were excluded, and further trials were performed after a further 2-minute rest period.

203

## 204 **Isometric Force-Time Curve Assessment**

205 Isometric force-time data was analysed via BMS software. The maximum force recorded  
206 during the 5-second bilateral and unilateral IMTP trials was reported as PF. Relative PF was  
207 calculated PF / body mass. Impulse at 100 (IP 100), 200 (IP 200), 250 (IP 250) and 300 (IP  
208 300) ms were also calculated (area under the force-time curve for each window) from onset  
209 of contraction (40 N threshold) and have demonstrated high reliability measures.<sup>25,27</sup>

## 210 **Statistical Analyses**

211 Statistical analysis was performed using SPSS software version 22 (SPSS, Chicago, Ill, USA)  
212 and a custom reliability spreadsheet.<sup>29</sup> Normality was confirmed for all variables using a  
213 Shapiro Wilks-test. Within-session reliability was assessed via intraclass correlation  
214 coefficients (ICC), 95% confidence intervals (CI), coefficient of variation (CV), typical error  
215 of measurement (TE) expressed as CV between the three trials for each dependant variable  
216 using a custom spreadsheet<sup>29</sup> and percentage change in mean. The CV was calculated based  
217 on the mean square error term of logarithmically transformed data.<sup>29</sup> Minimum acceptable  
218 reliability was determined with an ICC > 0.7 and CV < 10%.<sup>30,31</sup> Mean ± SD were calculated  
219 for all dependent variables.

220

221 Asymmetry index (imbalance between right and left limbs) was calculated by the formulae  
222 (right leg – left leg/ right leg × 100) for unilateral IMTP variables.<sup>9</sup> Asymmetry index for D  
223 and ND limbs was calculated by the formulae (dominant leg – non dominant leg/ dominant  
224 leg x 100) for unilateral IMTP variables, in accordance to previous research.<sup>9</sup> Limb  
225 dominance was defined as the limb that produced the highest isometric force-time value. To  
226 assess the magnitude of differences in force-time characteristics between limbs in male  
227 collegiate and professional rugby league players, paired sample t-tests and Cohen's *d* effect  
228 sizes were implemented. Effect sizes were calculated by the formula Cohen's  $d = M - M2/\sigma$   
229 pooled<sup>32</sup> and interpreted as trivial (<0.19), small (0.20–0.59), moderate (0.60–1.19), large  
230 (1.20–1.99), and very large (2.0–4.0).<sup>33</sup> The criterion for significance was set at  $p \leq 0.05$ .

## 231 **Results**

232

233 Intraclass correlation coefficients and CV demonstrated high within-session reliability for  
234 bilateral and unilateral IMTP PF (ICC = .94, CV = 4.7 – 5.5%) (Table 1). Lower reliability  
235 measures and greater variability were observed for bilateral and unilateral IMTP impulse at  
236 time bands (ICC = .81 - .88, CV = 7.7 - 11.8%) (Table 1). Unilateral IMTP left and right IP  
237 100 met minimum acceptable reliability criteria (ICC = .83 - .87, CV = 9.3 – 9.5%); **however**  
238 **IP 200, IP 250 and IP 300 demonstrated a greater level of variance than has previously been**  
239 **recommended (ICC= .82 - .88, CV = 10.3 – 11.6%).**<sup>32</sup> Descriptive statistics for bilateral and  
240 unilateral IMTP force-time characteristics are presented in Tables 2 and 3. Unilateral IMTP  
241 descriptive statistics, MSA indexes and ESs are presented in Tables 2 and 3.

242

243 **\*\*Insert Table 1 around here\*\***

244

## 245 **Professional Male Rugby League Players**

246 No significant differences ( $p > .05$ ,  $d \leq 0.11$ ) between right and left limbs were observed for  
247 all isometric force-time characteristics; with trivial differences between limbs (Table 2).

248 Conversely, small significant differences ( $p < .001$ ,  $d = 0.27 - 0.46$ ) were found between D  
249 and ND limbs for all isometric force-time characteristics (Table 3).

250

### 251 Collegiate Male Athletes

252 No significant differences ( $p > .05$ ,  $d \leq 0.32$ ) between right and left limbs were observed for  
253 all isometric force-time characteristics; with trivial to small differences between limbs (Table  
254 2). Conversely, small to moderate significant differences ( $p < .001$ ,  $d = 0.43 - 0.91$ ) were  
255 found between D and ND limbs for all isometric force-time characteristics (Table 3).

256

257 \*\*Insert Table 2 around here\*\*

258

259 \*\*Insert Table 3 around here\*\*

260

## 260 Discussion

261

262 The aims of this study were to assess the within-session reliability of bilateral and unilateral  
263 stance IMTP force-time characteristics and to determine if significant differences in isometric  
264 strength were present between lower limbs in male collegiate and male professional rugby  
265 league athletes. The results from this study demonstrated high-within session reliability for  
266 bilateral and unilateral stance IMTP PF meeting minimum acceptable reliability criteria.  
267 Lower reliability measures and greater variability were observed for unilateral IMTP IP 100,  
268 however still met minimum acceptable reliability criteria. **Conversely, unilateral IMTP IP  
269 200, IP 250 and IP 300 demonstrated a greater level of variance than has previously been  
270 recommended (Table 1).**<sup>32</sup> Trivial to small non-significant differences were observed between  
271 force-time characteristics for right and left limbs in collegiate and professional rugby league  
272 players (Table 2). However, small to moderate significant differences were revealed between  
273 D and ND limbs in male collegiate athletes and small significant differences between D and  
274 ND in professional rugby league players (Table 3). These findings are in agreement with our  
275 hypotheses.

276 The bilateral IMTP has been reported to be highly reliable with a low measurement error.<sup>24,</sup>  
277 <sup>25, 27</sup> Traditionally, IMTP assessments have been performed bilaterally, with asymmetries  
278 having only been established with the use of dual force platforms during bilateral IMTPs.<sup>11, 17,</sup>  
279 <sup>18</sup> To our knowledge, this study is the first to investigate a unilateral stance IMTP for the  
280 assessment of MSA indexes, demonstrating high reliability measures for isometric PF and  
281 lower reliability measures for impulse at time bands (Table 1). Further, significant differences  
282 were also observed between D and ND limbs (Table 3) for all isometric force-time  
283 characteristics. Therefore, this study revealed high within-session reliability for the  
284 assessment of unilateral stance IMTP PF and significant differences in force-time  
285 characteristics between D and ND limbs in male athletes (Table 3). However, a limitation of  
286 the present study is only the within-session reliability of the unilateral stance IMTP force-  
287 time characteristics was assessed, therefore, further research is required assessing between  
288 session test-retest reliability of the unilateral stance IMTP.

289

290 As previously stated limited studies have inspected unilateral multi-joint isometric strength  
291 through unilateral isometric squat assessments.<sup>13, 22, 23</sup> Hart et al<sup>22</sup> reported very high  
292 reliability measures of unilateral squat isometric PF (ICC = .96 - .98, CV = 3.6 - 4.7%) in 11  
293 male athletes. Spiteri et al<sup>23</sup> demonstrated similar reliability measures for unilateral isometric  
294 squat PF (ICC = .95, CV = 5.5 - 7%) in 12 male and 12 female athletes. Specifically, the

295 present study demonstrated comparable reliability measures for unilateral IMTP PF (ICC =  
296 .94, CV = 4.7 – 5.0%) to the above-mentioned studies in a large male sample (n = 54).  
297 Moreover, athletes may experience less discomfort when performing a unilateral IMTP in  
298 comparison to a unilateral isometric squat, due to pulling an immovable bar in comparison to  
299 pushing against an immovable bar positioned on the upper back (mid trapezius) during  
300 isometric squats. Consequently, the unilateral stance IMTP demonstrates high within-session  
301 reliability for PF assessments, with further research required into the between session  
302 reliability of unilateral PF.

303 This study is the first to inspect impulse at time bands (0-100, 0-200, 0-250, 0-300 ms) during  
304 unilateral stance IMTP assessments, demonstrating lower within-session reliability (ICC =  
305 .82 – .88, CV = 9.3 - 11.6%) and greater variability in contrast to PF reliability measures.  
306 Excluding IP 100, all unilateral stance impulse at time bands **demonstrated a greater level of**  
307 **variance than has previously been recommended.**<sup>32</sup> Dynamic tasks such as sprinting, jumping  
308 and changing direction are heavily dependent on an athlete’s capability to rapidly apply  
309 unilateral force over short time intervals,<sup>23, 27</sup> therefore the ability to assess an athlete’s  
310 unilateral force and impulse production capabilities via the unilateral stance IMTP may allow  
311 practitioners and scientists to identify any deficiencies in force production in specific limbs  
312 and also monitor the effectiveness of training interventions. Although it should be  
313 acknowledged that isometric and dynamic tasks are different. Our results indicate that the  
314 unilateral IP 100 demonstrates acceptable reliability, although practitioners should be aware  
315 greater variability may be observed when assessing impulse at alternative time bands (Table  
316 1).

317 No significant differences were observed between left and right limbs for isometric force-  
318 time characteristics in collegiate male athletes ( $p > .05$ ,  $d \leq 0.32$ ) and professional rugby  
319 league players ( $p > .05$ ,  $d \leq 0.11$ ). However, significant differences were observed when  
320 comparing D and ND limbs in male collegiate athletes ( $p < 0.001$ ,  $d = 0.43 – 0.91$ ) and  
321 professional rugby league players ( $p < .001$ ,  $d = 0.27 – 0.46$ ); highlighting that isometric  
322 strength deficits between lower limbs are present in male athletes. Future research is required  
323 establishing isometric MSA indexes in female athletes.

324

325 **\*\*Insert Figure 1 around here\*\***

326 **\*\*Insert Figure 2 around here\*\***

327

328

329 **The magnitudes of asymmetry in collegiate male athletes ( $6.2 \pm 4.8$  to  $11.5 \pm 9.5\%$ ) and**  
330 **professional rugby league players ( $5.1 \pm 3.8$  to  $9.6 \pm 8.6\%$ ) are presented in Table 3;**  
331 **individual PF imbalances are also illustrated in Figures 1 and 2. It should be noted that the**  
332 **that larger asymmetry values observed in the collegiate male athletes could be attributed to a**  
333 **heterogenous mixed sporting sample that contained athletes from sports where there are**  
334 **specific asymmetrical movement demands for example soccer, boxing and cricket which may**  
335 **result in the development of strength asymmetries.**<sup>34, 35</sup> **For example, Figure 2 illustrates the**  
336 **individual PF imbalance between D and ND limbs in collegiate male athletes, showing the**  
337 **boxers in this cohort demonstrated higher asymmetries in contrast to the other athletes from**  
338 **different which elevates the mean imbalance of this cohort.** It should also be acknowledged  
339 the results of this present study are only applicable and representative of the athletes at the  
340 specific time of the season they were tested; and are therefore likely to change over a

341 competitive season. Researchers have shown seasonal changes in fitness and strength  
342 characteristics throughout a season<sup>36, 37</sup> and the specific training phase has also shown to  
343 influence jump performance.<sup>38</sup> However, to our knowledge no literature exists investigating  
344 isometric strength asymmetries throughout a competitive season. Therefore, a future direction  
345 of research is to investigate seasonal variations in MSA as measured by the IMTP.

346 A strength discrepancy of 10-15% between limbs is considered to represent a potentially  
347 problematic asymmetry.<sup>2</sup> Although, no literature is available to substantiate this claim,<sup>8</sup> it is  
348 likely that the typical magnitude of MSA may vary between different muscle strength  
349 qualities for example concentric, eccentric, isometric and dynamic strength,<sup>14, 15</sup> and between  
350 different athlete populations.<sup>35</sup> Our findings provide normative MSA data for unilateral IMTP  
351 kinetics in different populations (Table 3). Athletes who demonstrate MSA greater than the  
352 values in Table 3 could therefore be considered asymmetrical.

353

354 Asymmetries during IMTP have only been established bilaterally with each foot on a separate  
355 force plate, with researchers observing asymmetries in isometric force time-characteristics in  
356 male and female athletes.<sup>11, 17-19</sup> Further, research suggests that weaker athletes display  
357 greater asymmetries in isometric force-time characteristics in comparison to stronger athletes  
358 during bilateral IMTPs<sup>17, 18</sup> and bilateral isometric squats<sup>16</sup> which may have a detrimental  
359 impact on vertical jumping performance.<sup>11</sup> Block periodised bilateral strength training has  
360 been reported to reduce bilateral asymmetries in weaker athletes;<sup>16</sup> highlighting the  
361 importance of maximising athletes bilateral strength to reduce the magnitude of bilateral  
362 MSA. It is unknown if this would be the case for unilateral IMTP MSA, thus future  
363 investigations are required determining the impact of strength training on unilateral IMTP  
364 MSA.

365

366 It should be noted that above-mentioned studies have inspected asymmetries during bilateral  
367 isometric squats and IMTPs and is therefore not a direct assessment of an isolated limb's  
368 force production capabilities. Consequently, a unilateral stance IMTP would allow the direct  
369 assessment of multi-joint isometric force production of a specific limb replicating unilateral  
370 stance of sprint, jumps and COD supported by the high reliability shown in the current  
371 findings. This will also help scientists and practitioners assess strength deficits between limbs  
372 and identify normative MSA values for athletic populations to benchmark standards in  
373 monitoring and strength assessments. Further, from a rehabilitation perspective a unilateral  
374 stance IMTP could be implemented to assess an athlete's isometric strength pre- and post-  
375 injury to determine the effectiveness training interventions and establish return to play  
376 criteria.

377

378 The impact of MSA on injury risk in athletes remains inconclusive;<sup>8</sup> however from a  
379 performance perspective it would be advantageous to be equally proficient in force  
380 production between limbs,<sup>14</sup> due to the unilateral requirements of sprinting, jumping, landing  
381 and change of directions. Previous studies have shown strength deficits between limbs can  
382 negatively impact performance during change of direction,<sup>10</sup> vertical jumping,<sup>11, 12</sup> and  
383 kicking.<sup>13</sup> Our results revealed significant differences in unilateral IMTP force-time  
384 characteristics between D and ND limbs in male athletes. However the implications of

385 unilateral IMTP MSA on dynamic performance such as jumping and COD is unknown, thus  
386 is an area of further research.

387

### 388 **Practical Applications**

389 Overall, this study confirmed that the unilateral stance IMTP produces high within-session  
390 reliability for PF and IP 100 also met minimum reliability criteria. Furthermore, small to  
391 moderate significant differences were observed between D and ND limbs for all isometric  
392 force-time characteristics with greater magnitudes of asymmetry of MSA in male collegiate  
393 athletes in comparison to professional rugby players. Male athletes with isometric force-time  
394 characteristics asymmetries greater than the **mean plus the SD of the normative MSA indexes**  
395 **presented in Table 3** maybe considered asymmetrical. Practitioners and scientists should  
396 therefore consider assessing athlete's unilateral isometric force production capabilities via a  
397 unilateral stance IMTP. This would permit the direct assessment of multi-joint isometric  
398 force production of the lower limbs replicating the unilateral stance of sprinting, jumping and  
399 COD; allowing practitioners to identify strength deficits between limbs so subsequent  
400 training programmes can be implemented to reduce the deficit which may reduce the  
401 likelihood of injury and improve athletic performance. From a rehabilitation perspective a  
402 unilateral stance IMTP would allow comparisons of lower limb strength and pre- and post-  
403 injury and also monitor the effectiveness of training interventions.

### 404 **Conclusion**

405 Bilateral and unilateral stance IMTP assessments demonstrated high within-session reliability  
406 for PF and lower although acceptable reliability measures for IP 100. Impulse at time bands  
407 (0-200, 0-250 and 0-300 ms) **demonstrated a greater level of variance than has previously**  
408 **been recommended**. No significant differences were observed between left and right limbs  
409 during unilateral stance IMTP for male collegiate and rugby league players however  
410 significant differences were revealed for all isometric force-time characteristics between D  
411 and ND limbs. Future research should focus on the effect of strength training on the  
412 magnitude of unilateral stance IMTP asymmetry and effect of isometric MSA on athletic  
413 performance.
