12 **Abstract**
13

14 Offender profiling follows the idea that if offenders' crime scene actions can be
15 empirically linked to their background characteristics, it will be possible to predict one from
16 the other (Canter, 2011). There is a lack of research exploring whether homicide offenders'
17 crime scene actions are predictive of their criminal histories, despite the potential utility of
18 such information (Almond, McManus, Bal, O'Brien, Rainbow, & Webb, 2018). The current
19 study addresses this gap in the literature.

28 A sample of 213 adult male-on-female homicides with sexual or unknown motive was
29 drawn from a UK-wide database. Relationships between 13 pre-conviction variables and 29
30 crime scene behaviors were explored using a bivariate statistical approach. Subsequently,
31 binary logistic regression models were used to predict the presence, or absence, of specific
32 pre-convictions based on a *combination* of offence behaviors. Analyses highlighted 16
33 statistically significant associations between key offence behaviors and previous convictions,
34 these associations were often "less likely" to result in previous conviction. The analysis failed
35 to find any association for various other variables, most notably sexual pre-convictions.

Introduction

The majority of homicides in the United Kingdom are solved relatively quickly after the offence occurred (Nicol, Innes, Gee, & Feist, 2004). In about one quarter of homicide cases, however, investigators are confronted with complex scenarios, in which possible suspects and relationships between involved individuals cannot be identified quickly (Francis et al., 2004). Homicides involving stranger or child victims, sexual elements, an unknown motive, or serial offences are usually more difficult to detect and consume considerable amounts of police resources, attract increased media attention, and are often perceived as especially severe, baring the potential to negatively impact the public's general fear of crime and, thus, their perceptions of police efficiency (Cole & Brown, 2014; Francis et al., 2004; Innes, 2003).

Within the UK, practitioners' experience in such difficult-to-solve cases is often complemented with empirically grounded investigative support provided by Behavioral Investigative Advisers (BIAs, Rainbow & Gregory, 2009). One of the core competencies of BIAs is their ability to make logical, evidence-based inferences on likely offender characteristics based on the behavioral assessment of a crime scene. This form of investigative support, commonly referred to as *offender profiling*, can be a valuable instrument to assist police in prioritising potential nominals and efficiently directing scarce resources in demanding investigations (Cole & Brown, 2014; Rainbow & Gregory, 2009). Offender profiling generally rests on the assumption of homology, i.e. offenders who commit crimes in a similar manner will also share similar background characteristics (Alison, Bennell, Mokros, & Ormerod, 2002; Mokros & Alison, 2002). Based on this tenet, offender profiling seeks to establish so-called "A to C equations", investigating *if* and *how* crime scene actions (A) can be linked to offender background characteristics (C), in order to allow for predictive inferences in unsolved criminal cases (Canter, 2011). With regard to practical

1
2
3 utility, profiling inferences made by BIAs should ideally relate to offender background
4
5 information that is overt, objective, and readily available to investigators, such as the
6
7 offender's likely age, sex, or previous criminal convictions (Alison et al., 2005). In addition,
8
9 investigative advice given by BIAs must be transparent as to how adequately and reliably it is
10
11 backed by scientific research (Alison, Smith, Eastman, & Rainbow, 2003; Almond, Alison, &
12
13 Porter, 2007). Taken together, this highlights the need for a broad and pragmatic research
14
15 foundation on which to base profiling claims on.
16
17
18

19
20 A number of international studies have extended the available evidence base for
21
22 offender profiling attempts in homicide cases over the last decades (e.g. Cole & Brown, 2014;
23
24 Francis et al., 2004; Fujita et al., 2016; Horning, Salfati, & Crawford, 2010; Salfati & Canter,
25
26 1999; Santtila, Häkkänen, Canter, & Elfgrén, 2003; Trojan & Salfati, 2011). However,
27
28 relatively few studies have examined *specifically* whether homicide offenders' *criminal*
29
30 *histories* can be inferred from their crime scene actions. Criminal history profiling follows the
31
32 idea that an offender's prior criminal experience, such as encounters with the criminal justice
33
34 system or previously successful criminal strategies, will influence future behaviors this
35
36 offender exhibits in the commission of a crime (Beauregard & Bouchard, 2010; Beauregard &
37
38 Martineau, 2013; Davies et al., 1997). The current lack of studies exploring links between
39
40 homicide offenders crimes scene actions and their pre-convictions is unfortunate given the
41
42 potential usefulness of such information to investigations, as 1) most homicide offenders
43
44 appear to have criminal antecedents of some kind (Broidy, Daday, Crandall, Sklar, & Jost,
45
46 2006; Cole & Brown, 2014; Greenall & Richardson, 2015; Soothill, Francis, Ackerley, &
47
48 Fligelstone, 2002) and 2) information on previous criminal convictions is easily available to
49
50 investigators through police databases as long as their offending has been in the UK (Alison
51
52 et al., 2005).

1
2
3 Furthermore, the few existing studies so far are divided by a fundamental dispute in
4 the general offender profiling literature, concerning which statistical approach should be
5 preferred for linking crime scene actions to offender characteristics (Alison, Goodwill,
6 Almond, Heuvel, & Winter, 2010). Some authors have favoured direct bivariate associations
7 to explore the relationship between single offence behaviors and prior offences (e.g. Almond
8 et al., 2018; Cole & Brown, 2014; Davies et al., 1997; Lea, Hunt, & Shaw, 2011; Scott,
9 Lambie, Henwood, & Lamb, 2006; ter Beek, van den Eshof, & Mali, 2010). In the context of
10 stranger rape, for example, Almond et al. (2018) found in their replication of the classic
11 Davies et al. (1997) study that stranger rapists who forced their entry were 2.5 times more
12 likely to have a previous conviction for burglary, whereas offenders who disabled their
13 victim's phone were nearly 5 times more likely to have previously been convicted for a
14 violent crime. Contrarily, other authors have employed a thematic approach, which
15 investigates how themes or typologies of crime scene actions relate to clusters of offender
16 characteristics (e.g. Horning et al., 2010; Salfati, 2000; Salfati & Canter, 1999; Santtila et al.,
17 2003; Trojan & Salfati, 2011). While the dispute over the most appropriate statistical
18 approach for offender profiling might not yet be ultimately resolved, there is some evidence
19 that direct bivariate associations outperform thematic approaches in their predictive power
20 (Goodwill, Alison, & Beech, 2009).

60
Despite the general dearth of research and the ongoing methodological dispute, some
studies have shed light on possible relationships between offence behaviors and previous
convictions in the context of homicide (e.g. Cole & Brown, 2014; Horning et al., 2010; Salfati
& Canter, 1999; Trojan & Salfati, 2011). Employing a direct, bivariate statistical approach on
a sample of difficult-to-detect homicide cases, Cole and Brown (2014) found, for example,
that killers who were under the influence of alcohol or drugs during the offence, were more
than twice as likely to have a previous conviction for violent offences, whereas murderers

1
2
3 who took pieces of their victim's clothing with them were nearly 2.5 times more likely to
4
5 have been previously arrested for a sexual offence. Using a more thematic approach, Horning
6
7 et al. (2010) demonstrated that homicide offenders, who showed some degree of
8
9 specialisation towards violent, sexual, or acquisitive crimes in their criminal histories, were
10
11 more likely to engage in goal directed behaviors at the crime scene, such as controlling the
12
13 victim or sexually and materially exploitative behaviors, when compared to non-specialist
14
15 offenders.
16
17

18
19 However, the majority of the existing studies thus far are arguably based on non-
20
21 contemporary samples and have either contained a limited number of previous conviction
22
23 categories (Cole & Brown, 2014) or have grouped multiple previous convictions into broader
24
25 clusters or typologies (Horning et al., 2010; Salfati & Canter, 1999; Trojan & Salfati, 2011).
26
27 Thus, exploring a larger and more specific set of previous conviction variables may help to
28
29 not only answer whether offenders' criminal histories can be reliably predicted from their
30
31 crime scene actions, but also whether certain pre-convictions may be better suited for
32
33 prediction than others. In addition, previous studies have mostly analysed samples including
34
35 both male and female killers, even though research has repeatedly highlighted differences in
36
37 crime scene behaviors, criminal histories, and general psychological functioning between the
38
39 two groups (Jurik & Winn, 1990; Putkonen, Weizmann-Henelius, Lindberg, Rovamo, &
40
41 Häkkänen-nyholm, 2011; Trägårdh, Nilsson, Granath, & Sturup, 2016). Similarly, prior
42
43 studies indicate that offenders with female victims may differ from killers that target male
44
45 victims (Muftić & Baumann, 2012), indicating more extensive arrest records and differences
46
47 in weapon involvement and methods of killing in femicide offenders (Goetting, 1991). There
48
49 may, therefore, be a need to specialise predictive profiling efforts towards what appear to be
50
51 distinct homicidal offender sub-populations.

1
2
3 In conclusion of the theoretical, practical, and methodological considerations outlined
4 above, the study proposed here aimed to explore the relationships between a large set of
5 homicide offender pre-convictions and specific crime scene behaviors using a bivariate
6 statistical approach. The sample utilised was focussed on a large, yet specific homicide
7 offender sub-group, i.e. adult male-on-female offenders with adult victims. To increase the
8 practical applicability of any findings, this study used a contemporary sample of investigative
9 policing data drawn from a database of hard-to-solve homicide cases with sexual or unknown
10 motive. In doing so, this study addresses the need for a separate, offence-specific, up-to-date
11 empirical basis BIAs can refer to when aiming at predicting an unknown offender's likely
12 criminal history in cases of unsolved homicide.

28 **Method**

29 **Database**

30
31 The present study is based on secondary case data provided by the National Crime
32 Agency's (NCA) Serious Crime Analysis Section (SCAS). SCAS operates a unique, UK-wide
33 database holding details of rape, homicide, and abduction cases that meet specific criteria. For
34 homicide, these criteria include cases where BIA support may typically be requested, i.e.
35 homicides with a known sexual motive as well as homicides with unknown motive, in which
36 the offender-victim relationship is unknown or stranger (Rainbow & Gregory, 2009). SCAS
37 receive case files from all UK police forces, which are then coded and entered into a Violent
38 Crime Linkage Analysis System (ViCLAS) database involving a rigorous quality control
39 process and highly trained staff to ensure input accuracy and interrater reliability (Almond et
40 al., 2018). The dataset utilised herein was provided to the author in a clean, pre-coded, and
41 anonymised form.

Sample

For this study, a sample of solved homicide cases involving a single female victim and a single male offender was drawn from ViCLAS by SCAS based on the following criteria: First, offences must have occurred between 1985 and 2017. Second, both victim and offender must have been adults (above the age of 16) at the time of the offence. Third, data must be taken from cases involving single offenders and single victims only. And finally, for serial homicides, only the first victim must be included in the dataset to avoid any biases resulting from an overrepresentation of certain serial offenders. After eliminating four cases in which no pre-conviction information was available, a final sample of 213 cases was obtained.

Sample demographics show that on average, offenders ($M = 31.38$, $SD = 9.42$) were younger than victims ($M = 37.83$, $SD = 19.95$) with most offenders being of European descent (89.2%), in relation to offenders of African Caribbean (6.1%), Asian (2.8%), and Oriental or Arabic (1.4%) descent. One offender was classified as of unknown descent (0.5%). Table 1 displays the frequencies of relationships between offenders and their victims in this sample.

Procedure

Variables extracted from ViCLAS related to either *previous convictions* of the offender at the time of the index offence or specific *behavioral offence characteristics* that were observed at the crime scene. Offence behavior variables were pre-coded by SCAS in a dichotomous format with 1 indicating presence and 0 indicating absence (or unknown status) of specific behaviors and crime scene characteristics. A total of 29 offence behavior variables (see Table 2) broadly falling into the categories of *sexual behaviors*, *weapon involvement*, *method of killing*, *body disposal*, *theft*, *precautions*, and *other behaviors*, were selected for the analysis based on a number of previous studies on homicide (Cole & Brown, 2014; Greenall & Richardson, 2015; Pell, 2017; Wright, 2017).

1
2
3 Some low frequency variables (e.g. different recorded types of vaginal penetration)
4 were combined into broader, superordinate categories (e.g. general vaginal penetration).
5
6 Notably, variables relating to precautions taken were grouped to reflect whether offenders
7
8 manipulated the *crime scene* (e.g. destroyed forensics), the *victim* (e.g. blindfolding, gagging),
9
10 or *themselves* (e.g. wearing gloves, condoms) to avoid detection or facilitate the offence.
11
12 Variables relating to the method of killing (blunt force, sharp force, asphyxia/strangulation)
13
14 and variables concerning theft from the crime scene (personal items, valuables, clothing
15
16 stolen) were coded from free text boxes by the author. It should be noted that in cases of
17
18 homicide, it is generally unlikely to obtain a complete and exhaustive picture of a killer's
19
20 offence behaviors solely through observing the crime scene. This implicates that 1) the
21
22 absence of a recorded variable does not necessarily equal the absence of the respective
23
24 behavior, and 2) the presence of a recorded variable cannot guarantee that the offender carried
25
26 out that behavior
27
28
29
30
31
32
33

34 In addition to these offence behavior variables, a total of 13 pre-convictions (see Table 3)
35
36 were selected, based on variables used in previous studies on sexual homicide (Greenall &
37
38 Richardson, 2015) and rape (Almond et al., 2018).
39
40
41
42
43

44 **Statistical Analysis**

45
46 This study aimed to replicate the methodology originally introduced by Davies et al.
47
48 (1997) for their investigation of stranger rapists' pre-convictions in a new context – that of
49
50 male-on-female homicide offenders. Specifically, this study adopted the statistically more
51
52 sophisticated approach recently employed by Almond, et al. (2018) in their contemporary
53
54 replication of the Davies et al. (1997) study.
55
56
57
58
59
60

1
2
3 Data was analysed in two stages. In *stage one*, separate chi-square tests were
4 employed to investigate whether any direct associations between offence behavior variables
5 and conviction variables could be identified. Where test assumptions were violated (expected
6 frequencies must be > 5 in each cell), Fisher's exact tests were used (Field, 2013). In order to
7 account for multiple testing on the same sample, Bonferroni-Holm corrections were applied to
8 adjust p-values. To further qualify any significant associations, Odds Ratios (OR) were
9 calculated to assess the likelihood of an offender having a specific pre-conviction based on
10 the presence or absence of single behaviors during the offence. An $OR > 1$ indicates that the
11 probability of a pre-conviction A is increased if an offence behavior B was observed, whereas
12 the probability of A is decreased if B was not observed (and vice versa for $ORs < 1$)
13 (Lieberman, 2005). According to Chen, Cohen, and Chen (2010), the strength of the identified
14 associations can be considered low ($OR < 1.5$), medium ($OR 1.5 - 5$), or high ($OR > 5$).

18
19
20
21
22
23
24
25
26
27
28
29

30 In *stage two*, logistic regression models were used to predict an offender's previous
31 convictions based on a combination of significant offence behavior variables identified in
32 stage one. A separate forced-entry logistic regression was performed for each pre-conviction
33 type. In addition, it was assessed how much each predictor variable contributed to the
34 predictive accuracy of the model and if these contributions were statistically significant. To
35 evaluate their usefulness to practitioners, each of the models' ability to predict a certain pre-
36 conviction was compared with the "best guess" investigators would face without knowledge
37 of any offence behavior (i.e. a guess based only on the base rate of a particular pre-conviction
38 in this sample). As an additional measure of model performance, Receiver Operating
39 Characteristics (ROC) Area Under the Curve (AUC) values were calculated.

Descriptive Statistics

Table 2 displays the frequency of offence behavior variables in this sample. While only a minority of offenders had previous convictions for sexual crimes (14.6%), the majority of cases in this dataset (73.2%) can be classified as sexual homicides based on behaviors observed from the crime scene, according to the criteria proposed by Ressler et al. (1988). More specifically, most of the cases involved some degree of disrobement of the victim (66.2%), whereas overt sexual behaviors (41.8%) and injuries to victims' sexual areas (16.4%) were less commonly observed. A relatively large group of offenders in this sample engaged in some form of theft from the victim (44.1%). Similarly, a sizeable minority took precautions in relation to the homicide crime (40.8%).

Frequencies of offenders' previous convictions are displayed in Table 3. Most offenders (73.7%) had been convicted at least once prior to the index homicide, with theft (45.1%), violence (39.0%), burglary (35.2%), and criminal damage (33.3%) being the most frequent conviction categories. However, there is also a sizeable minority of offenders (26.3%) without any previous criminal history.

Exploring Male-on-Female Homicide Offenders' Behaviors and Conviction Histories

To explore whether any bivariate associations between single crime scene behaviors and specific pre-convictions could be found, chi-square analyses were conducted. No significant associations were found for several crime scene behavior variables as well as the pre-conviction variables *criminal record*, *drugs*, *public order*, *robbery* and *sexual crimes*, whereas *arson* and *homicide* were excluded from the analysis due to their extremely low frequency within this sample. A total of 16 statistically significant relationships ($p < .05$) were obtained, for which Table 4 shows Odds Ratios as a measure of effect size and direction.

Precautionary behaviors.

If an offender took *precautions relating to the crime scene*, he was nearly 3 times less likely (OR < 1, therefore $1/0.36 = 2.78$) to have a previous conviction for *weapon-related crimes*, $\chi^2(1) = 4.213, p = .040$.

Sexual behaviors.

If *vaginal penetration* did occur during the homicide, the likelihoods of several pre-convictions were reduced significantly, with *theft*, $\chi^2(1) = 5.910, p = .015$, and *violence*, $\chi^2(1) = 4.626, p = .031$, being 2 times and *weapon-related crimes* nearly 2.5 times less likely, $\chi^2(1) = 4.039, p = .044$. Similarly, pre-convictions for *violent crimes* were 2.5 times less likely if the offender *moved the victim's clothing to expose her*, $\chi^2(1) = 4.054, p = .044$. Contrarily, a previous conviction for *fraud* was 2 times more likely if the victim was found *naked*, $\chi^2(1) = 3.885, p = .049$.

Weapon involvement.

If there was evidence that an offender *brought a weapon* to the crime scene, pre-convictions for *criminal damage*, $\chi^2(1) = 4.034, p = .045$, and *theft*, $\chi^2(1) = 4.996, p = .025$, were about 2.5 times less likely, whereas prior *violence-related* convictions were nearly 3.5 times less likely, $\chi^2(1) = 7.094, p = .008$. However, the use of a *bludgeoning weapon* increased offenders' likelihood of having a previous conviction for *fraud*, $\chi^2(1) = 5.102, p = .024$, making it more than 2 times as likely.

Method of killing.

Killing the victim through *blunt force* increased an offender's likelihood of having a previous *criminal damage* conviction, $\chi^2(1) = 4.393, p = .036$, making it nearly twice as likely. Associated in the opposite direction, *weapon-related* pre-convictions were almost 3.5 times less likely, $\chi^2(1) = 7.561, p = .006$, if death was caused through *asphyxia/strangulation*.

Other behaviors.

The use of a *vehicle* in association with the index homicide made a pre-conviction for *criminal damage* nearly 2.5 times *less* likely $\chi^2(1) = 5.932, p = .015$. If the offence comprised an element of *arson*, the likelihood of prior convictions for *violent crimes* ($p = .030$), and *burglary* ($p = .010$), were increased (due to the low frequency of arson as an offence element, Fisher's exact tests are reported). Similarly, a *burglary* pre-conviction was more than 2.5 times *more* likely if a *burglary element* was present in the index homicide, $\chi^2(1) = 8.213, p = .004$.

After applying Bonferroni-Holm corrections (dividing the uncorrected $\alpha = .05$ by the number dependent variables $k = 11, \alpha_{corr.} = .0045$), only the association of *burglary element* with *burglary* pre-conviction reached statistical significance. Therefore, results obtained so far should be interpreted with caution.

Logistic Regression Models

The significant bivariate associations identified in the first step of the analysis were then entered into binary logistic regression models to predict the presence or absence of a specific pre-conviction based on a *combination* of offence behaviors.

Burglary.

Using a logistic regression model, it was attempted to predict whether offenders did or did not have a previous conviction for *burglary* based on the presence or absence of a *burglary element* in the index homicide offence (see Table 5). While the variable *arson element* was also found to be associated with burglary pre-convictions in the previous step, it had to be excluded from the logistic regression analysis as it violated basic assumptions of the model (expected cell frequencies were less than 5 in more than 20% of cells if arson element was included). The remaining one-factorial model reached statistical significance, $\chi^2(1) = 7.925, p = .005$, with *burglary element* contributing significantly to the model

1
2
3 ($p = .005$), as indicated by the Wald criterion. The whole model explained between 3.7%
4
5 (Cox and Snell R^2) and 5.0% (Nagelkerke R^2) of the variance in the dependent variable
6
7 burglary pre-conviction, correctly classifying 66.2% of all cases.
8
9

15 **Criminal Damage.**

16
17 Two of the three previously identified crime scene behaviors, namely *vehicle used* and
18
19 *death blunt force*, were entered into a logistic regression (see Table 5) to predict the presence
20
21 or absence of a *criminal damage* pre-conviction (*weapon brought by offender* was excluded
22
23 due to violations of model assumptions). The resulting model reached statistical significance,
24
25 $\chi^2(2) = 10.801, p = .005$, with both *vehicle used* ($p = .016$) and *death blunt force* ($p = .034$)
26
27 contributing significantly to the model. Overall, the model correctly classified 66.7% of all
28
29 cases, explaining between 4.9% (Cox and Snell R^2) and 6.9% (Nagelkerke R^2) of the variance
30
31 in the pre-conviction variable *criminal damage*.
32
33
34
35
36
37

38 **Fraud.**

39
40 The two significant crime scene behaviors of *victim naked* and *bludgeoning weapon*
41
42 were entered into a logistic regression model (see Table 5) to predict whether offenders did or
43
44 did not have a previous *fraud* conviction, with the resulting model being statistically
45
46 significant, $\chi^2(2) = 8.450, p = .015$, and both *victim naked* ($p = .050$) and *bludgeoning weapon*
47
48 ($p = .026$) contributing significantly to the model. The full model accounted for between 3.9%
49
50 (Cox and Snell R^2) and 6.0% (Nagelkerke R^2) of the variance in *fraud* pre-conviction status,
51
52 correctly classifying 78.9% of all cases.
53
54
55
56
57
58
59
60

Theft.

Chi-square analyses previously identified two crime scene behaviors to be significantly associated with *theft* pre-conviction status. A logistic regression model (see Table 5) including both variables (*vaginal penetration* and *weapon brought by offender*) reached statistical significance, $\chi^2(2) = 11.474, p = .003$, and both *vaginal penetration* ($p = .014$) and *weapon brought by offender* ($p = .025$) made significant contributions to the prediction. This model correctly classified 61.0% of the cases and explained between 5.2% (Cox and Snell R^2) and 7.0% (Nagelkerke R^2) of the variance in *theft* pre-conviction status.

Weapons.

The crime scene behaviors *precautions scene*, *vaginal penetration*, and *death asphyxia/strangulation* were identified as significantly related with *weapon-related pre-convictions*. Except for *vaginal penetration* (excluded due to violation of assumptions), all of these variables were entered into a logistic regression model (see Table 5) that reached statistical significance, $\chi^2(2) = 13.533, p = .001$, with both *precautions scene* ($p = .039$) and *death asphyxia/strangulation* ($p = .007$) contributing significantly to the model. In total, the model classified 81.7% of the cases correctly and accounted for between 6.2% (Cox and Snell R^2) and 10.0% (Nagelkerke R^2) of the variance in *weapons* pre-conviction status.

Violence.

Of the four crime scene behaviors previously identified to be associated with *violence-related pre-convictions*, only *vaginal penetration* and *weapon brought by offender* were included in a logistic regression model as depicted in Table 5 (*arson element* and *clothing moved to expose* were excluded due to violations of model assumptions). This model successfully predicted the pre-conviction variable *violence*, $\chi^2(2) = 12.795, p = .002$, and both *vaginal penetration* ($p = .028$) and *weapon brought by offender* ($p = .009$) contributed

1
2
3 significantly to the model. Correctly classifying 61.0% of all cases, the model accounted for
4
5 between 5.8% (Cox and Snell R^2) and 7.9% (Nagelkerke R^2) of the variance in *violence pre-*
6
7 *conviction* status.
8
9

10 11 **Prediction and performance of logistic regression models** 12

13
14 Mirroring the original Davies et al. (1997) paper, Table 11 shows the logit values of
15
16 all logistic regression models produced in the current study. These models predict the
17
18 probability of whether an offender does or does not have a specific pre-conviction based on
19
20 the presence or absence of a combination of crime scene behavior for each case in the sample
21
22 using a model equation. To predict the probability of a *theft* pre-conviction in a case in which,
23
24 for example, the offender engaged in *vaginal penetration*, but did not *bring a weapon* to the
25
26 crime scene, the log-odds would equal:
27
28

$$29 \quad .171 \text{ (constant)} - .768 * 1 \text{ (vaginal penetration)} - .949 * 0 \text{ (weapon)} = - .597.$$

30
31 The probability of a theft pre-conviction would then be:
32
33

$$34 \quad \frac{e^{-.597}}{1 + e^{-.597}} \quad \text{or} \quad 35.5\%.$$

35
36
37 In terms of model performance, the percentage of cases correctly classified by the logistic
38
39 regression models based on their probability estimations using crime scene information
40
41 (criterion: > 50% vs. < 50%) is only slightly higher (*burglary, theft*) or equal (*criminal*
42
43 *damage, fraud, weapons, violence*) to the performance of a simple “best guess” approach that
44
45 uses only base-rate pre-conviction information of this sample (e.g. probability of an offender
46
47 having a *fraud* pre-conviction irrespective of his crime scene behavior is 21.1%). As an
48
49 additional measure of the models’ discriminant performances, ROC AUC analyses were
50
51 conducted. AUC values displayed in Table 6 are equivalent to the probability with which
52
53 proposed logistic regression models will assign a randomly chosen case, in which the offender
54
55 *did* have a certain pre-conviction, with a higher probability estimation than a randomly chosen
56
57
58
59
60

1
2
3 case, in which the offender *did not* have this pre-conviction (Fawcett, 2006). AUC
4
5 probabilities range from 58.4% (*burglary*) to 66.2% (*weapons*), suggesting overall poor to
6
7 medium model performances (Rice & Harris, 2005)
8
9
10
11

12 **Discussion**

13
14 The purpose of this study was to explore whether male-on-female homicide offenders'
15
16 criminal histories could be predicted from their crime scene actions. By using a contemporary
17
18 set of investigative policing data and a large number of previous conviction variables, this
19
20 study aimed at extending the available evidence-base for criminal history profiling in cases of
21
22 hard-to-solve homicide. The present research successfully demonstrated that 1) single crime
23
24 scene actions could be empirically linked to single previous conviction variables using a
25
26 bivariate statistical approach and that 2) multivariate statistical models were able to predict
27
28 the probability of a specific pre-conviction based on a combination of offence behaviors
29
30 observed from the crime scene. This study, therefore, successfully replicated the
31
32 methodological approach proposed by Davies et al. (1997) and later Almond et al. (2018) in a
33
34 new criminal context, i.e. hard-to-solve male-on-female homicide cases. Theoretical and
35
36 practical implications of the obtained results are proposed and discussed with regard to a
37
38 number of methodological limitations.
39
40
41
42
43

44 First, results suggest that not all prior convictions may be similarly suited for
45
46 prediction based on behavioral characteristics of a crime scene. While this study was
47
48 successful in linking *some* pre-conviction variables to certain offence behaviors, it failed to
49
50 find any empirical association for several other pre-convictions, namely *criminal record*,
51
52 *drugs*, *public order*, *robbery*, and *sexual crimes*. The general finding that only some pre-
53
54 convictions seem to be related to offence behaviors is mirrored in previous studies that have
55
56 used a similar bivariate linking approach (e.g. Almond et al., 2018; Cole & Brown, 2014),
57
58
59
60

1
2
3 which lends some support to the assumption that the link between offender characteristics and
4 crime scene behaviors in general may be highly idiosyncratic. Accordingly, it has been argued
5 that homology as the core tenet of offender profiling (i.e. two offenders who commit a certain
6 type of crime in a similar way will show similar characteristics) may only be valid for *specific*
7 offence behaviors and *single* offender characteristics (e.g. Taylor, Snook, Bennell, & Porter,
8 2015; ter Beek et al., 2010). This opposes the idea that broader offence behavior clusters (e.g.
9 themes) could be empirically associated with a standard set of background characteristics (e.g.
10 offender types), which indeed has proven difficult in prior research (Mokros & Alison, 2002;
11 Trojan & Salfati, 2011). Therefore, it is argued here that further efforts are needed to isolate
12 and understand *direct* links between key offence behaviors and individual background
13 characteristics.

14
15 In the context of criminal history profiling, the few existing studies exploring these
16 direct, bivariate relationships, however, differ in their findings on which pre-convictions
17 *exactly* could and could not be linked to crime scene behaviors. While both this study and
18 Almond et al. (2018), for example, did not find any association between offence variables and
19 a history of sexual crime, Cole and Brown (2014) found prior sexual offences to be positively
20 associated with the lack of precautionary behaviors at the scene and theft of clothing from the
21 victim. More studies will be needed to establish, whether some (and if so, *which*) pre-
22 convictions may generally be better suited for prediction from crime scene behaviors than
23 others, and whether differences exist with regard to the type of crime (e.g. rape vs. homicide),
24 or subsamples of offenders (e.g. male vs. female offenders, targeting female vs. male
25 victims).

26
27 Among the key findings in the current study is the association of crimes containing a
28 *burglary element* with a prior conviction for *burglary* (more than 2.5 times more likely). This
29 finding is consistent with evidence for criminal specialisations among homicide offenders,
30
31

1
2
3 which highlights a large sub-group displaying histories of predominantly instrumental crimes,
4 such as *theft*, *burglary*, or *robbery* (Trojan & Salfati, 2016). As most homicides in the current
5 study contained overt, or covert sexual behaviors (73.2%), it is interesting to note that for
6 cases of stranger rape, the crime scene behavior *forced entry* has been identified as a
7 significant predictor of prior convictions for acquisitive crime types (i.e. *burglary*, *theft*,
8 *robbery*) in multiple studies (Almond et al., 2018; Davies et al., 1997; Scott et al., 2006).
9
10 Previous research has further highlighted a link between sexual homicide and a history of
11 burglary (e.g. Schlesinger & Revitch, 1999), with some authors suggesting that repeat
12 burglary offenders may escalate from non-contact burglaries towards burglaries featuring
13 more serious, interpersonal offence elements depending on a number of circumstantial factors
14 (Pedneault, Harris, & Knight, 2015). Taken together, *burglary elements* within homicides and
15 serious sexual crimes appear as key indicators of previous *burglary* crimes in the literature,
16 even though a generalisation of this finding towards other types of acquisitive crimes (e.g.
17 *theft*, *robbery*) could not be supported in the current study.

59
60

Interestingly, sexual behaviors were predominantly negatively associated with prior conviction variables in this sample. If *vaginal penetration* was observed, the likelihoods of prior *theft*, *weapons*, and *violence* pre-convictions were reduced, whereas *clothing moved* further decreased the likelihood of prior *violence* convictions. An exemption was found in prior *fraud* convictions being two times *more* likely if the *victim was found naked*. These findings have not yet been recorded, given that prior bivariate criminal history profiling studies either did not examine specific sexual behaviors (Almond et al., 2018), or did not find any relationships between sexual behaviors and prior convictions (Cole & Brown, 2014). Similarly, behaviors indicating some degree of premeditation were also negatively associated with pre-conviction variables in the current sample, with *weapon brought* decreasing the likelihood of prior *theft*, *violence*, and *criminal damage* convictions and *weapon-related* pre-

1
2
3 convictions being less likely if *precautions concerning the crime scene* were observed. While
4
5 it may be tempting to derive *theoretical* implications from the present findings, it should be
6
7 borne in mind that this study was very much exploratory and was neither conceptualised to
8
9 explicitly test nor retrospectively allow for inferences on underlying psychological constructs
10
11 that may explain the cause for the identified associations. This is generally the case in studies
12
13 employing a direct, bivariate profiling approach (Crabbé et al., 2008). However, the present
14
15 study's success in finding some offence behaviors predictive of homicide offenders' pre-
16
17 convictions has important *practical* implications.
18
19

20
21 In unsolved cases of homicide, the availability of an empirical basis that allows to
22
23 estimate the probability of an offender having a certain pre-conviction based on his behaviors
24
25 at the crime scene would undoubtedly be beneficial to the investigation. Using the predictive
26
27 models identified in this study, such probabilities could be calculated at the beginning of an
28
29 investigation. Outcomes may assist in prioritising potential nominals according to the degree
30
31 of similarity between theirs and the most likely criminal history of the offender, as predicted
32
33 by the models. Similarly, the statistical models proposed here may suggest new lines of
34
35 enquiry if, for example, not all predictive behaviors included in the models have yet been
36
37 confirmed as present or absent in a given investigation. Overall, this study may not only
38
39 contribute to improving detection rates of homicide offences, it may also increase the
40
41 efficiency with which police resources are allocated in homicide investigations, thereby
42
43 reducing the time and financial efforts associated with apprehending offenders (Alison et al.,
44
45 2010; Rainbow & Gregory, 2009). Most importantly, the present findings are therefore
46
47 directly relevant to the work of BIAs by providing an evidence base on which they are
48
49 required to base their investigative claims and inferences on (Alison et al., 2003; Almond et
50
51 al., 2007). The practical utility of the results obtained herein is, however, qualified by a
52
53 variety of limitations.
54
55
56
57
58
59
60

Limitations

First, some statistical issues should be noted regarding the results in this study. To identify, which crime scene behaviors were significantly related to which offender pre-convictions, this study utilised multiple chi-squared tests, but only *one* of the identified relationships (*burglary element* with prior *burglary* conviction) remained significant after applying Bonferroni-Holm corrections. As the probability of obtaining false positive results is inflated when large numbers of tests are performed on the same sample (Asendorpf et al., 2013), it may, therefore, be that this study has identified some variables as linked, when in fact, they are not. Furthermore, while the sample in this study can be considered large ($N = 213$) regarding the context of hard-to-solve homicide, the sample size was relatively small in comparison to other studies that rely on logistic regression models (Cramer, 1999), resulting in the parameter estimations of the present models being less stable and potentially susceptible to biases (Field, 2013; Nemes, Jonasson, Genell, & Steineck, 2009).

Second, measures of predictive accuracy indicated that the complex logistic regression models utilised in this study had an overall poor to medium performance, making them only slightly better than a guess based solely on pre-conviction frequencies in this sample. While this highlights the value of simple base rate information for offender profiling efforts, the models provided herein may still be useful in rare cases, in which crime scene behaviors indicate a divergence from the base rate norm (e.g. probability of *theft* pre-conviction > 50% if no *vaginal penetration* and no *weapon brought* vs. 45% base rate).

On a more conceptual level, this study was based on solved homicide cases only, therefore, excluding those offenders who may be most proficient in avoiding detection. It has been argued that measures other than prior convictions, such as previous charges or arrests, may be more indicative of an offender's criminal history (Almond et al., 2018). Therefore, generalisations from the current findings should be treated with some degree of caution.

1
2
3 Caution is further advisable, as the data used herein was not explicitly collected for research
4 purposes, but ultimately stemmed from police records. Although the data is subject to a
5 rigorous quality control process before being entered into the SCAS database, the
6 completeness of the data cannot be guaranteed, especially regarding the level of detail
7 requested for some of the offence behavior variables. Although all behaviors that were
8 evident would have been coded, due to the fact that the victim is not able to report on the
9 offender's behavior in a homicide, there is the potential that not all behaviors that occurred in
10 the offence were coded. As this piece of applied research was conceptualised as a practical
11 instrument for police investigations, reliance on policing data may arguably increase the
12 ecological validity of this study (Mokros & Alison, 2002).
13
14
15
16
17
18
19
20
21
22
23
24
25

26 There is also a potential bias in the results towards those who do not have a substantial
27 previous criminal history. As behaviors such as sexual behaviors and weapon brought to the
28 scene are more likely to be recorded due to forensic evidence i.e. semen or weapon left at the
29 scene may be biased towards those that are less criminally competent which may then be
30 reflected in their criminal history. There may be plenty of other cases with similar behaviors
31 that occurred in the offence but are not evident – and this may be a reflection of the
32 perpetrator's criminal competence/sophistication/history.
33
34
35
36
37
38
39
40
41

42 Finally, the proposed statistical models were constructed to optimise their predictive
43 accuracy in the current sample, which may contain random errors and other idiosyncrasies,
44 especially with regard to the small sample size (Levine, Blair, & Carpenter, 2017). It is
45 therefore important to validate the findings on a separate sample, in order to determine
46 accuracy shrinkage and predictive performance for new cases, that were not used to construct
47 the models (Cole & Brown, 2014; ter Beek et al., 2010). As the present sample is exhaustive
48 and contains all homicide cases that matched the inclusion criteria in the UK, further research
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 would have to either rely on data from other countries or future cases from within the UK,
4
5 raising questions of regional or temporal comparability between the samples.
6
7

8 **Conclusion**

9

10 In conclusion, this study has provided a broad empirical overview on links between a
11 large set of offender criminal history variables and crime scene behaviors in cases of
12 homicide. By proposing statistical models that allow for predictions of the most likely
13 criminal history of an offender as indicated by his specific offence behaviors, the current
14 results may be of practical utility to homicide investigations. However, as several statistical
15 and conceptual limitations of this study must be considered, it is argued here that the current
16 results should only be used for practical applications with appropriate caution and
17 transparency towards the study's shortcomings. In the UK, this transparency is ensured by
18 experienced BIAs through providing observational grounds, warrants, research backing,
19 rebuttal(s), and an indication of strength for each advisory investigative claim made,
20 following the principles of Toulmin's philosophy of argument (Alison et al., 2003; Rainbow,
21 2008). In this way, BIA advice can be useful to inform and justify subsequent decisions made
22 by investigators. This approach enables a synergy of evidence-based research, such as the
23 present one, and investigators' practical experience, which is ultimately directed at
24 maximising efficiency and success in criminal investigations.

Table 1

Frequency of relationship categories between offenders and their victims.

Offender-victim relationship	n	(%)
Stranger	71	(33.3)
Friend/associate	37	(17.4)
Romantic partner	35	(16.4)
Prostitute	25	(11.7)
Unknown	21	(9.9)
Peripheral contact	11	(5.2)
Romantic ex-partner	9	(4.2)
Family	4	(1.9)

Table 2. *Frequencies of offenders' crime scene behaviors during the index homicide.*

Offence Behavior Variables	n	(%)
Precautionary behaviors		
<i>Any precautions taken^a</i>	87	(40.8)
Precautions scene	55	(25.8)
Precautions victim	28	(13.1)
Precautions offender	16	(7.5)
Sexual behaviors		
<i>Any overt sexual behaviors^a</i>	89	(41.8)
Vaginal penetration	67	(31.5)
Anal penetration	30	(14.1)
Oral penetration	8	(3.8)
Other sexual activity	24	(11.3)
Offence Behavior Variables	n	(%)
<i>Any disrobement^a</i>	141	(66.2)
Victim naked	56	(26.3)
Victim partially disrobed	52	(24.4)
Clothing moved to expose	34	(16.0)
Injury to sexual areas	35	(16.4)
<i>Sexual homicide^{a, b}</i>	156	(73.2)
Body disposal		
Body recovered indoors	113	(53.1)
Body concealed	53	(24.9)
Body dismembered	18	(8.5)
Weapon involvement		
<i>Any weapon involved^a</i>	142	(66.7)
Stabbing weapon	73	(34.3)
Bludgeoning weapon	45	(21.1)
Ligature weapon	44	(20.7)
Weapon taken from scene	56	(26.3)
Weapon brought by offender	33	(15.5)
Theft		
<i>Any theft^a</i>	94	(44.1)
Theft valuables	77	(36.2)
Theft personal	34	(16.0)
Theft clothing	28	(13.1)
Method of killing		
Death blunt force	81	(38.0)
Death asphyxia/strang.	73	(34.3)
Death sharp force	49	(23.0)
Other behaviors		
Vehicle used	55	(25.8)
Overkill	47	(22.1)
Burglary element	45	(21.1)
Arson element	9	(4.2)

Notes. ^a Variables printed in italics are collapsed behavior categories for descriptive purposes and were not included in the statistical analysis. ^b Cases were classified by the author as sexual homicides according to the criteria proposed by Ressler et al. (1988).

Table 3. *Frequencies of offenders' previous convictions at the time of the index homicide.*

Conviction Variables	n	(%)
Criminal record	157	(73.7)
Theft	96	(45.1)
Violence	83	(39.0)
Burglary	75	(35.2)
Criminal damage	71	(33.3)
Public order	48	(22.5)
Fraud	45	(21.1)
Weapons	39	(18.3)
Sexual	31	(14.6)
Robbery	26	(12.2)
Drugs	25	(11.7)
Arson	10	(4.7)
Homicide	8	(3.8)

Table 4

Odds Ratios for significant associations between crime scene behavior and conviction variables.

	Burglary	Criminal Damage	Fraud	Theft	Weapons	Violence
Precautions scene					0.36	
Vaginal penetration				0.48	0.42	0.51
Victim naked			2.01			
Clothing moved to expose						0.43
Weapon brought by offender		0.39		0.40		0.30
Bludgeoning weapon			2.30			
Death blunt force		1.86				
Death asphyxia/strang.					0.29	
Vehicle used		0.41				
Burglary element	2.62					
Arson element	7.00					5.89

Notes. Only Odds Ratios for bivariate associations that reached statistical significance ($p < .05$) are shown.

Table 5

Crime scene behaviors differentiating offenders with and without a pre-convictions.

	Burglary Pre-conviction		
	Yes (<i>n</i> = 75)	No (<i>n</i> = 138)	Sig.
Burglary element	32.0%	15.2%	.005
	Criminal Damage Pre-conviction		
	Yes (<i>n</i> =71)	No (<i>n</i> =142)	
Vehicle used	15.5%	31.0%	.016
Death blunt force	47.9%	33.1%	.034
	Fraud Pre-conviction		
	Yes (<i>n</i> =45)	No (<i>n</i> =168)	
Victim naked	37.8%	23.2%	.050
Bludgeoning weapon	33.3%	17.9%	.026
	Theft Pre-conviction		
	Yes (<i>n</i> =96)	No (<i>n</i> =117)	
Vaginal penetration	22.9%	38.5%	.014
Weapon brought by offender	9.4%	20.5%	.025
	Weapons Pre-conviction		
	Yes (<i>n</i> =39)	No (<i>n</i> =174)	
Precautions scene	12.8%	28.7%	.039
Death asphyxia/strang.	15.4%	38.5%	.007
	Violence Pre-conviction		
	Yes (<i>n</i> =83)	No (<i>n</i> =130)	
Vaginal penetration	22.9%	36.9%	.028
Weapon brought by offender	7.2%	20.8%	.009

Table 6

Logit values, AUCs, and percentage improvements in correctly predicted cases compared to a base rate “best guess” for logistic regression models.

	Burglary	Criminal Damage	Fraud	Theft	Weapons	Violence
<i>Model constant</i>	-.830	-.744	-1.744	.171	-.954	-.076
Precautions scene					-1.061	
Vaginal penetration				-.768		-.710
Victim naked			.712			
Weapon brought by offender				-.949		-1.246
Bludgeoning weapon			.847			
Death blunt force		.640				
Death asphyxia/strang.					-1.274	
Vehicle used		-.915				
Burglary element	.964					
AUC	.584	.623	.626	.624	.662	.622
<i>[95% CI]</i>	<i> [.502, .666]</i>	<i> [.545, .701]</i>	<i> [.532, .721]</i>	<i> [.549, .699]</i>	<i> [.576, .748]</i>	<i> [.547, .697]</i>
Difference to “best guess” in % correct	+1.4%	—*	—*	+6.1 %	—*	—*

Note. * No difference between % pre-convictions predicted correctly using logistic regression model and % correct using only base-rate information from the sample.
